Revised Edition published September, 1922

PREFACE TO THE FIRST EDITION

THE significance of the Calculus, the possibility of applying it in other fields, its usefulness, ought to be kept constantly and vividly before the student during his study of the subject, rather than be deferred to an uncertain future.

Not only for students who intend to become engineers, but also for those planning a profound study of other sciences, the usefulness of the Calculus is universally recognized by teachers; it should be consciously realized by the student himself. It is obvious that students interested primarily in mathematics, particularly if they expect to instruct others, should recognize the same fact.

To all these, and even to the student who expects only general culture, the use of certain types of applications tends to make the subject more real and tangible, and offers a basis for an interest that is not artificial. Such an interest is necessary to secure proper attention and to insure any real grasp of the essential ideas.

For this reason, the attempt is made in this book to present as many and as varied applications of the Calculus as it is possible to do without venturing into technical fields whose subject matter is itself unknown and incomprehensible to the student, and without abandoning an orderly presentation of fundamental principles.

The same general tendency has led to the treatment of topics with a view toward bringing out their essential usefulness. Thus the treatment of the logarithmic derivative is

vitalized by its presentation as the relative rate of change of a quantity; and it is fundamentally connected with the important "compound interest law," which arises in any phenomenon in which the relative rate of increase (logarithmic derivative) is constant.

Another instance of the same tendency is the attempt, in the introduction of the precise concept of curvature, to explain the reason for the adoption of this, as opposed to other simpler but cruder measures of bending. These are only instances, of two typical kinds, of the way in which the effort to bring out the usefulness of the subject has influenced the presentation of even the traditional topics.

Rigorous forms of demonstration are not insisted upon, especially where the precisely rigorous proofs would be beyond the present grasp of the student. Rather the stress is laid upon the student's certain comprehension of that which is done, and his conviction that the results obtained are both reasonable and useful. At the same time, an effort has been made to avoid those grosser errors and actual misstatements of fact which have often offended the teacher in texts otherwise attractive and teachable.

Thus a proof for the formula for differentiating a logarithm is given which lays stress on the very meaning of logarithms; while it is not absolutely rigorous, it is at least just as rigorous as the more traditional proof which makes use of the limit of $(1+{}^1/_n)^n$ as n becomes infinite, and it is far more convincing and instructive. The proof used for the derivative of the sine of an angle is quite as sound as the more traditional proof (which is also indicated), and makes use of fundamentally useful concrete concepts connected with circular motion. These two proofs again illustrate the tendency to make the subject

vivid, tangible, and convincing to the student; this tendency will be found to dominate, in so far as it was found possible, every phase of every topic.

Many traditional theorems are omitted or reduced in importance. In many cases, such theorems are reproduced in exercises, with a sufficient hint to enable the student to master them. Thus Taylor's Theorem in several variables, for which wide applications are not apparent until further study of mathematics and science, is presented in this manner.

On the other hand, many theorems of importance, both from mathematical and scientific grounds, which have been omitted traditionally, are included. Examples of this sort are the brief treatment of simple harmonic motion, the wide application of Cavalieri's theorem and the prismoid formula, other approximation formulas, the theory of least squares (under the head of exercises in maxima and minima), and many other topics.

The Exercises throughout are colored by the views expressed above, to bring out the usefulness of the subject and to give tangible concrete meaning to the concepts involved. Yet formal exercises are not at all avoided, nor is this necessary if the student's interest has been secured through conviction of the usefulness of the topics considered. Far more exercises are stated than should be attempted by any one student. This will lend variety, and will make possible the assignment of different problems to different students and to classes in successive years. It is urged that care be taken in selecting from the exercises, since the lists are graded so that certain groups of exercises prepare the student for other groups which follow; but it is unnecessary that all of any group be assigned, and it is urged that in general less than

half be used for any one student. Exercises that involve practical applications and others that involve bits of theory to be worked out by the student are of frequent occurrence. These should not be avoided, for they are in tune with the spirit of the whole book; great care has been taken to select these exercises to avoid technical concepts strange to the student or proofs that are too difficult.

An effort is made to remove many technical difficulties by the intelligent use of tables. Tables of Integrals and many other useful tables are appended; it is hoped that these will be found usable and helpful.

Parts of the book may be omitted without destroying the essential unity of the whole. Thus the rather complete treatment of Differential Equations (of the more elementary types) can be omitted. Even the chapter on Functions of Several Variables can be omitted, at least except for a few paragraphs, without vital harm; and the same may be said of the chapter on Approximations. The omission of entire chapters, of course, would only be contemplated where the pressure of time is unusual; but many paragraphs may be omitted at the discretion of the teacher.

Although care has been exercised to secure a consistent order of topics, some teachers may desire to alter it; for example, an earlier introduction of transcendental functions and of portions of the chapter on Approximations may be desired, and is entirely feasible. But it is urged that the comparatively early introduction of Integration as a summation process be retained, since this further impresses the usefulness of the subject, and accustoms the student to the ideas of derivative and integral before his attention is diverted by a variety of formal rules.

Purely destructive criticism and abandonment of coherent arrangement are just as dangerous as ultra-conservatism. This book attempts to preserve the essential features of the Calculus, to give the student a thorough training in mathematical reasoning, to create in him a sure mathematical imagination, and to meet fairly the reasonable demand for enlivening and enriching the subject through applications at the expense of purely formal work that contains no essential principle.

E. W. Davis,
W. C. Brenke,
E. R. Hedrick, Editor.

June, 1912.

PREFACE TO THE REVISED EDITION

THE Davis Calculus was very favorably received by the mathematical world at the time of its original appearance in 1912. The necessity for some revision arose from the usual exhaustion of the old lists of exercises by repeated use of them in class-rooms, and from suggestions of minor changes of forms and of arrangement of the textual matter as a result of actual experience in its use. Professor Davis was intending such a revision at the time of his death, and it has remained for Professor Brenke, in collaboration with Professor E. R. Hedrick, to carry it out.

The lists of exercises have been thoroughly revised. Most of the old formal exercises have been replaced by new ones, the lists have been extended or shortened, as experience indicated they should be, and some of the applications formerly contained in the lists of problems have been transferred to the body of the text.

The spirit of the original text was to bring out to the student the real significance of the Calculus; and this was accomplished in an unusually effective manner. In the revision, every effort has been made to retain and to amplify this spirit. The technique, and mechanical drill, have not been neglected, but the reasons for learning this technique have been demonstrated to the student unmistakably.

Some rearrangement of topics has occurred. Thus integration as a summation has been postponed until after the technique of integration has been mastered. The latter half of the book has been somewhat simplified, and a few more

difficult topics that were not reached by many classes have been omitted. It is hoped that the revision will appeal to many and that it will do justice to the great teacher who was the principal author of the original edition.

W. C. Brenke,
E. R. Hedrick.

TABLES

THE CALCULUS

CHAPTER I

FUNCTIONS — SLOPE — SPEED

1. Variables. Constants. Functions. A quantity which changes is called a ***variable.*** The temperature at a given place, the annual rainfall, the speed of a falling body, the distance from the earth to the sun, are variables.

A quantity that has a fixed value is called a ***constant.*** Ordinary numbers, such as $2/3$, $\sqrt{2}$, -7, π, $\log 5$, etc., are constants.

If one variable, y, depends on another variable, x, in such a way that y is determined when x is known, y is called a ***function*** of x; the variable x is called the ***independent variable,*** and y is called the ***dependent variable.*** Thus the area A of a square is a function of the side s of the square, since $A = s^2$. The volume of a sphere is a function of the radius. In general, a mathematical expression that involves a variable x is a function of that variable.

2. The Function Notation. A very useful abbreviation for a function of a variable x consists in writing $f(x)$ (read f of x) in place of the given expression.

Thus if $f(x) = x^2 + 3x + 1$, we may write $f(2) = 2^2 + 3 \cdot 2 + 1 = 11$, that is, the value of $x^2 + 3x + 1$ when $x = 2$ is 11. Likewise $f(3) = 19$, $f(-1) = -1$, $f(0) = 1$, etc. $f(a) = a^2 + 3a + 1$. $f(u + v) = (u + v)^2 + 3(u + v) + 1$.

Other letters than f are often used, to avoid confusion, but f is used most often, because it is the initial of the word *func-*

tion. Other letters than x are often used for the variable. In any case, given $f(x)$, to find $f(a)$, simply substitute a for x in the given expression.

3. Graphs. In our study of variables and functions, much use will be made of graphs. To draw the graph of an equation that contains two variables, we may determine by trial several pairs of numbers which satisfy the equation and plot these number pairs as points of the graph, as in elementary analytic geometry.

Shorter methods for drawing certain graphs are indicated in some of the following exercises. Thus to draw the graph of the equation

$$y = \sin x + \cos x,$$

first draw on the same sheet of paper the graphs of the two equations

$$y = \sin x \quad \text{and} \quad y = \cos x,$$

and add the corresponding ordinates.

Certain standard graphs are shown in the tables at the back of this book.

EXERCISES

Calculate the values of each of the following functions for a suitably chosen set of values of x, and draw the graph. Estimate the values of x and $f(x)$ at points where the curve has a highest or a lowest point. Also determine graphically the solutions of the equation $f(x) = 0$.

1. $f(x) = x^2 - 5x + 2.$
2. $f(x) = x^3 - 2x + 4.$
3. $f(x) = x^4 - 5x^3 + 3x^2 - 2x + 3.$
4. $f(x) = (x + 1)/(2x - 3).$
5. $f(x) = \log_{10} x.$
6. $f(x) = (\log_{10} x)^2.$
7. $f(x) = \sin x.$
8. $f(x) = \csc x.$
9. $f(x) = \cos x.$
10. $f(x) = \sin x + \cos x.$
11. $f(x) = x + \sin x.$
12. $f(x) = \sin 2x.$

13. If $f(x) = \sin x$ and $\phi(x) = \cos x$, show that $[f(x)]^2 + [\phi(x)]^2 = 1$; $f(x) \div \phi(x) = \tan x$; $f(x+y) = f(x)\,\phi(y) + f(y)\,\phi(x)$; $\phi(x+y) = ?$; $f(x) = \phi(\pi/2 - x)$; $\phi(x) = f(\pi/2 - x) = -\phi(\pi - x)$; $f(-x) = -f(+x)$; $\phi(-x) = \phi(x)$.

14. If $f(x) = \log_{10} x$, show that

$$f(x) + f(y) = f(x \cdot y); \qquad f(x^2) = 2f(x);$$
$$f(m/n) - f(n/m) = 2f(m) - 2f(n); \qquad f(m/n) + f(n/m) = 0.$$

15. If $f(x) = \tan x$, $\phi(x) = \cos x$, draw the curves $y = f(x)$, $y = \phi(x)$, $y = f(x) - \phi(x)$. Mark the points where $f(x) = \phi(x)$ and estimate the values of x and y there.

16. Taking $f(x) = x^2$, compare the graph of $y = f(x)$ with that of $y = f(x) + 1$, and with that of $y = f(x+1)$.

17. Taking any two curves $y = f(x)$, $y = \phi(x)$, how can you most easily draw $y = f(x) - \phi(x)$? $y = f(x) + \phi(x)$? Draw $y = x^2 + 1/x$.

18. How can you most easily draw $y = f(x) + 5$? $y = f(x+5)$? assuming that $y = f(x)$ is drawn.

19. Draw $y = x^2$ and show how to deduce from it the graph of $y = 2x^2$; the graph of $y = -x^2$.

Assuming that $y = f(x)$ is drawn, show how to draw the graph of $y = 2f(x)$; that of $y = -f(x)$.

20. From the graph of $y = x^2$, show how to draw the graph of $y = (2x)^2$; that of $y = x^2 + 2$; that of $y = (x+2)^2$; that of $y = (2x - 3)^2$.

21. What is the effect upon a curve if, in the equation, x and y are interchanged? Compare the graphs of $y = f(x)$, $x = f(y)$.

Plot each of the following curves:

22. $y + 1 = \sin(3x - 2)$.

23. $y = 2^x + \sin x$.

24. $y = 2^x + 2^{-x}$.

25. $y = 2^{-x}\cos x$.

Plot each of the following curves, using polar coördinates.

26. $r = \sin\theta$

27. $r = \sin 2\theta$.

28. $r = \cos 3\theta$.

29. $r = 3 + 2\sin\theta$.

30. $r = 2 + 3\sin\theta$.

31. $r = 1 + \cos\theta$.

32. $r = \theta$.

33. $r = 1/\theta$.

34. $r = 2^\theta$.

35. $r = 2^{-\theta}$.

4. Rate of Increase. Slope. In the study of any quantity, its rate of increase (or decrease), when some related quantity changes, is a very important consideration.

Graphically, the rate of increase of y with respect to x is shown by the rate of increase of the height of a curve. If the curve is very flat, there is a small rate of increase; if steep, a large rate.

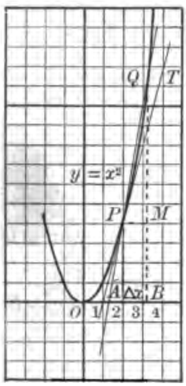

FIG. 1.

The ***steepness***, or ***slope***, of a curve shows the rate at which the dependent variable is increasing with respect to the independent variable. When we speak of the slope of a curve at any point P, we mean the slope of its tangent at that point. To find this, we must start, as in analytic geometry, with a *secant* through P. Let the equation of the curve, Fig. 1, be $y = x^2$, and let the point P at which the slope is to be found, be the point $(2, 4)$. Let Q be any other point on the curve, and let Δx represent the difference of the values of x at the two points P and Q.*

Then in the figure, $OA = 2$, $AB = \Delta x$, and $OB = 2 + \Delta x$. Moreover, since $y = x^2$ at every point, the value of y at Q is $BQ = (2 + \Delta x)^2$. The slope of the secant PQ is the quotient of the differences Δy and Δx:

$$\tan \angle MPQ = \frac{\Delta y}{\Delta x} = \frac{MQ}{PM} = \frac{(2 + \Delta x)^2 - 4}{\Delta x} = 4 + \Delta x.$$

The slope m of the tangent at P, that is $\tan \angle MPT$, is the

* Δx may be regarded as an abbreviation of the phrase, "difference of the x's." The quotient of two such differences is called a ***difference quotient***. Notice particularly that Δx does *not* mean $\Delta \times x$. Instead of "difference of the x's," the phrases "change in x" and "increment of x" are often used.

limit of the slope of the secant as Q approaches P. But it is clear that this limit as Q approaches P is 4, since Δx approaches zero when Q approaches P. Hence the slope m of the curve is 4 at the point P. At any other point the argument would be similar. If the coördinates of P are (a, a^2), those of Q would be $[(a + \Delta x), (a + \Delta x)^2]$; and the slope of the secant would be the difference quotient $\Delta y \div \Delta x$:

$$\frac{\Delta y}{\Delta x} = \frac{(a + \Delta x)^2 - a^2}{\Delta x} = \frac{2\,a\,\Delta x + \overline{\Delta x}^2}{\Delta x} = 2\,a + \Delta x.$$

Hence the slope of the curve at the point (a, a^2) is *

$$m = \lim_{\Delta x \to 0} \Delta y/\Delta x = \lim_{\Delta x \to 0} (2\,a + \Delta x) = 2\,a.$$

On the curve $y = x^2$, the slope at any point is numerically twice the value of x. When the slope can be found, as above, the *equation of the tangent* at P can be written down at once, by analytic geometry, since the slope m and a point (a, b) on a line determine its equation:

$$y - b = m\,(x - a).$$

The *normal* to a curve is defined to be the line through a point on the curve perpendicular to the tangent line at that point. Hence, if the slope of the tangent at a point (a, b) is m, the slope of the normal is $-1/m$, and the *equation of the normal* is

$$y - b = -\frac{1}{m}(x - a).$$

Thus, in the preceding example, at the point (2, 4), where we found $m = 4$, the equation of the tangent is

$$(y - 4) = 4\,(x - 2), \quad \text{or} \quad 4\,x - y = 4.$$

The equation of the normal is

$$y - 4 = -\tfrac{1}{4}\,(x - 2), \quad \text{or} \quad x + 4\,y = 18.$$

* Read "$\Delta x \to 0$" "as Δx approaches zero." A discussion of limits is given in Chapter II.

5. General Rules. A part of the preceding work holds true for any curve, and all of the work is at least similar. Thus, for any curve, the slope is

$$m = \lim_{\Delta x \to 0} (\Delta y / \Delta x);$$

that is, the slope m of the curve is the limit of the difference quotient $\Delta y / \Delta x$.

The changes in various examples arise in the calculation of the difference quotient, $\Delta y \div \Delta x$, and of its limit, m.

This difference quotient is always obtained, as above, by finding the value of y at Q from the value of x at Q, from the equation of the curve, then finding Δy *by subtracting from this the value of y at P, and finally forming the difference quotient by dividing* Δy *by* Δx.

6. Slope Negative or Zero. If the slope of the curve is *negative*, the rate of increase in its height is negative, that is, the height is really *decreasing* with respect to the independent variable.*

If the slope is *zero*, the tangent to the curve is *horizontal*. This is what happens ordinarily at a highest point (maximum) or at a lowest point (minimum) on a curve.

EXAMPLE 1. Thus the curve $y = x^2$, as we have just seen, has, at any point $x = a$, a slope $m = 2a$. Since m is positive when a is positive, the curve is rising on the right of the origin; since m is negative when a is negative, the curve is falling (that is, its height y decreases as x increases) on the left of the origin. At the origin $m = 0$; the origin is the lowest point (a minimum) on the curve, because the curve falls as we come toward the origin and rises afterwards.

* Increase or decrease in the height is always measured as we go toward the right, *i.e.* as the independent variable increases.

EXAMPLE 2. Find the slope of the curve

(1) $$y = x^2 + 3x - 5$$

at the point where $x = -2$; also in general at a point $x = a$. Use these values to find the equation of the tangent at $x = 2$; the tangent at any point.

When $x = -2$, we find $y = -7$ (P in Fig. 2); taking any second point Q, $(-2 + \Delta x, -7 + \Delta y)$, its coördinates must satisfy the given equation, therefore

$$-7 + \Delta y = (-2 + \Delta x)^2 + 3(-2 + \Delta x) - 5,$$

or

$$\Delta y = -4\,\Delta x + \overline{\Delta x}^2 + 3\,\Delta x = -\Delta x + \overline{\Delta x}^2,$$

where $\overline{\Delta x}^2$ means the square of Δx. Hence the slope of the secant PQ is

$$\Delta y/\Delta x = -1 + \Delta x.$$

The slope m of the curve is the limit of $\Delta y/\Delta x$ as Δx approaches zero; *i.e.*

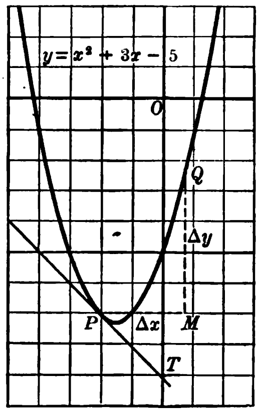

FIG. 2.

$$m = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \to 0} (-1 + \Delta x) = -1.$$

It follows that the equation of the tangent at $(-2, -7)$ is

$$(y + 7) = -1\,(x + 2), \text{ or } x + y + 9 = 0.$$

Likewise, if we take the point P (a, b) in any position on the curve whatsoever, the equation (1) gives

$$b = a^2 + 3a - 5.$$

Any second point Q has coördinates $(a + \Delta x, b + \Delta y)$ where Δx and Δy are the differences in x and in y, respectively, between P and Q. Since Q also lies on the curve, these coördinates satisfy (1):

$$b + \Delta y = (a + \Delta x)^2 + 3(a + \Delta x) - 5.$$

Subtracting the last equation from the preceding,

$$\Delta y = 2a\,\Delta x + \overline{\Delta x}^2 + 3\,\Delta x, \text{ whence } \Delta y/\Delta x = (2a + 3) + \Delta x,$$

and

$$m = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \to 0} [(2a + 3) + \Delta x] = 2a + 3.$$

Therefore the tangent at (a, b) is

$$y - (a^2 + 3a - 5) = (2a + 3)(x - a), \text{ or } (2a + 3)x - y = a^2 + 5.$$

The slope m is zero when $2a + 3 = 0$, *i.e.* when $a = -3/2$. Hence the tangent is horizontal at the point where $x = -3/2$.

EXAMPLE 3. Consider the curve $y = x^3 - 12x + 7$. If the value of x at any point P is a, the value of y is $a^3 - 12a + 7$. If the value of x at Q is $a + \Delta x$, the value of y at Q is $(a + \Delta x)^3 - 12(a + \Delta x) + 7$.

Hence

$$\frac{\Delta y}{\Delta x} = \frac{[(a + \Delta x)^3 - 12(a + \Delta x) + 7] - [a^3 - 12a + 7]}{\Delta x}$$
$$= (3a^2 + 3a\,\Delta x + \overline{\Delta x}^2) - 12,$$

and

$$m = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = 3a^2 - 12.$$

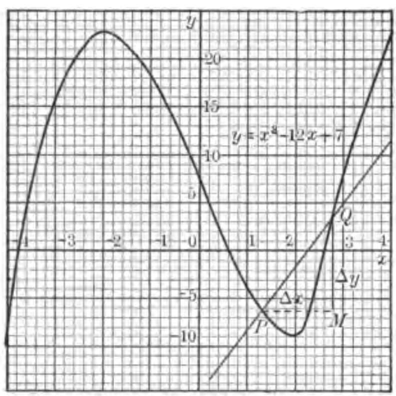

FIG. 3.

For example, if $x = 1$, $y = -4$; at this point $(1, -4)$ the slope is $3 \cdot 1^2 - 12 = -9$; and the equation of the tangent is

$$(y + 4) = -9(x - 1), \text{ or } 9x + y - 5 = 0.$$

The points at which the slope is zero would be determined by the equation $m = 3a^2 - 12 = 0$, which gives $a = \pm 2$. When x has either of these values, the tangent is horizontal. From the equation of the curve, if $x = +2$, $y = -9$; when $x = -2$, $y = 23$. Hence the horizontal tangents are at the points $(2, -9)$ and $(-2, 23)$. (See Fig. 3.)

EXERCISES

Find the slope and the equation of the tangent line to each of the following curves at the point indicated. Verify each result by drawing the graph of the curve and the graph of the tangent line from their equations.

1. $y = x^2 - 2$; $(1, -1)$.
2. $y = x^2/2$; $(2, 2)$.
3. $y = 2x^2 - 3$; $(2, 5)$.
4. $y = x^2 - 4x + 3$; $(2, -1)$.
5. $y = x^3$; $(1, 1)$.
6. $y = x^3 - 9x$; $(2, -10)$.
7. $y = x^3 - 3x + 4$; $(0, 4)$.
8. $y = 2x^3 - 3x^2$; $(1, -1)$.

Draw each of the following curves, using for greater accuracy the precise values of x and y for which the tangent is horizontal, and the knowledge of the values of x for which the curve rises or falls.

9. $y = x^2 + 5x - 5$.
10. $y = 3x - x^2$.
11. $y = x^3 - 3x + 2$.
12. $y = x^3 - x^2$.
13. $y = x^3 - 6x$.
14. $y = x^3 - 6x + 5$.
15. $y = x^4$.
16. $y = x^4 - 2x^2$.
17. $y = x^4 - x^3$.

7. Speed. An important case of rate of change is the rate at which a body moves, — its speed.

Consider the motion of a body falling from rest under the influence of gravity. During the first second it passes over 16 ft., during the next it passes over 48 ft., during the third over 80 ft. In general, if t is the number of seconds, and s the entire distance it has fallen, $s = 16t^2$ if the gravitational constant g be taken as 32. The graph of this equation (see Fig. 4) is a parabola with its vertex at the origin.

The speed, that is the rate of increase of the space passed over, is the slope of this curve, *i.e.*

$$\lim_{\Delta t \to 0} \frac{\Delta s}{\Delta t}.$$

This may be seen directly in another way. The *average* speed for an interval of time Δt is found by dividing the difference between the space passed over at the beginning and at

the end of that interval of time by the difference in time: *i.e.* the average speed is the difference quotient $\Delta s \div \Delta t$. By the ***speed at a given instant*** we mean *the limit of the average speed* over an interval Δt beginning or ending at that instant as that interval approaches zero, *i.e.*

$$\textit{speed} = \lim_{\Delta t \to 0} \frac{\Delta s}{\Delta t}.$$

Taking the equation $s = 16\,t^2$, if $t = 1/2$, $s = 4$ (see point P in Fig. 4). After a lapse of time Δt, the new values are

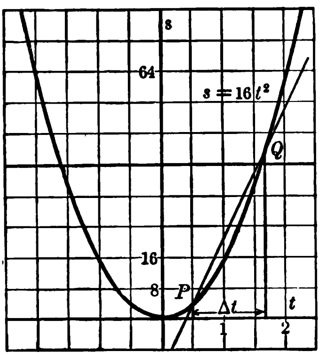

FIG. 4.

$$t = 1/2 + \Delta t,$$

and $$s = 16\,(1/2 + \Delta t)^2$$

(Q in Fig. 4).

Then

$$\begin{aligned}\Delta s &= 16\,(1/2 + \Delta t)^2 - 4\\ &= 16\,\Delta t + 16\,\overline{\Delta t}^2,\\ \Delta s/\Delta t &= 16 + 16\,\Delta t.\end{aligned}$$

Whence

$$\begin{aligned}\textit{speed} &= \lim_{\Delta t \to 0} \frac{\Delta s}{\Delta t}\\ &= \lim_{\Delta t \to 0}\,(16 + 16\,\Delta t) = 16;\end{aligned}$$

that is, the speed at the end of the first half second is 16 ft. per second.

Likewise, for any value of t, say $t = T$, $s = 16\,T^2$; while for $t = T + \Delta t$, $s = 16\,(T + \Delta t)^2$; hence

$$\textit{average speed} = \frac{\Delta s}{\Delta t} = \frac{16\,(T + \Delta t)^2 - 16\,T^2}{\Delta\,t} = 32\,T + 16\,\Delta t$$

and $$\textit{speed} = \lim_{\Delta t \to 0} \frac{\Delta s}{\Delta t} = 32\,T.$$

Thus, at the end of two seconds, $T = 2$, and the speed is $32 \cdot 2 = 64$, in feet per second.

8. Component Speeds. Any curve may be regarded as the path of a moving point. If a point P does move along a curve, both x and y are fixed when the time t is fixed. To

specify the motion completely, we need equations which give the values of x and y in terms of t.

The ***horizontal speed*** is the rate of change of x with respect to the time. This may be thought of as the speed of the projection M of P on the x-axis. Likewise, the ***vertical speed*** is the rate of change of y with respect to the time. It would be the speed of the projection of P on the y-axis. Hence, by § 7, we have

$$\textit{horizontal speed} = \lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t},$$

and

$$\textit{vertical speed} = \lim_{\Delta t \to 0} \frac{\Delta y}{\Delta t}.$$

Since

$$\frac{\Delta y}{\Delta x} = \frac{\Delta y}{\Delta t} \div \frac{\Delta x}{\Delta t},$$

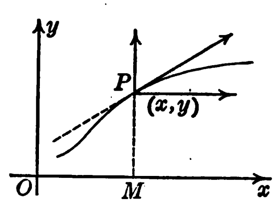

FIG. 5.

it follows that

$$m = (\textit{vertical speed}) \div (\textit{horizontal speed});$$

that is, the slope of the curve is the ratio of the rate of increase of y to the rate of increase of x.

9. Continuous Functions. In §§ 4–8, we have supposed that the curves used were *smooth*. All of the functions which we have used could be represented by smooth curves. Except perhaps at isolated points, a small change in the value of one coördinate has caused a small change in the value of the other coördinate. Throughout this text, unless the contrary is expressly stated, the functions dealt with will be of the same sort. Such functions are called ***continuous.*** (See § 10, p. 14.)

The curve $y = 1/x$ is continuous except at the point $x = 0$. The curve $y = \tan x$ is continuous except at the

points $x = \pm \pi/2$, $\pm 3\pi/2$, etc. Such exceptional points occur frequently. We do not discard a curve because of them, but it is understood that any of our results may fail at such points.

EXERCISES

1. From the formula $s = 16t^2$, calculate the values of s when $t = 1$, 2, 1.1, 1.01, 1.001. From these values calculate the average speed between $t = 1$ and $t = 2$; between $t = 1$ and $t = 1.1$; between $t = 1$ and $t = 1.01$; between $t = 1$ and $t = 1.001$. Show that these average speeds are successively nearer to the speed at the instant $t = 1$.

2. Calculate as in Ex. 1 the average speed for smaller and smaller intervals of time after $t = 2$; and show that these approach the speed at the instant $t = 2$.

3. A body thrown vertically downwards from any height with an original velocity of 50 ft. per second, passes over in time t (in seconds) a distance s (in feet) given by the equation $s = 50t + 16t^2$ (if $g = 32$, as in § 7). Find the speed v at the time $t = 1$; at the time $t = 2$; at the time $t = 4$; at the time $t = T$.

4. In Ex. 3 calculate the average speeds for smaller and smaller intervals of time after $t = 0$; and show that they approach the original speed $v_0 = 50$. Repeat the calculations for intervals beginning with $t = 2$.

Calculate the speed of a body at the times indicated in the following possible relations between s and t:

5. $s = t^2$; $t = 1, 3, 20, T$.

6. $s = 16t^2 - 50t$; $t = 0, 2, T$.

7. $s = -16t^2 + 80t$; $t = 0, 2, 5$.

8. $s = t^3 - 6t + 4$; $t = 0, 1/2, 1$.

9. The relation in Ex. 7 holds (approximately, since $g = 32$ approximately) for a body thrown upward with an initial speed of 80 ft. per second, where s means the distance from the starting point counted positive upwards. Draw a graph which represents this relation between the values of s and t.

In this graph mark the greatest value of s. What is the value of v at that point? Find *exact* values of s and t for this point.

10. A body thrown horizontally with an original speed of 8 ft. per second falls in a vertical plane curved path so that the values of its hori-

zontal and its vertical distances from its original position are respectively, $x = 8\,t$, $y = 16\,t^2$, where y is measured downwards. Show that the vertical speed is $32\,T$, and that the horizontal speed is 8, at the instant $t = T$. Eliminate t to show that the path is the curve $4\,y = x^2$.

11. Find the component speeds and the resultant speed when the path is given by the equations

$$x = t + 1,\ y = t^2 - 1.$$

Calculate their numerical values when $t = 1$; when $t = 0$; when $t = 2$. Plot the path.

12. Proceed as in Ex. 11 when the path is given by the equations

$$x = 2 + t^2,\ y = 2 - t^2.$$

CHAPTER II

LIMITS — DERIVATIVES

10. Limits. Infinitesimals. We have been led in what precedes to make use of limits. Thus the tangent to a curve at the point P is defined by saying that its slope is the *limit* of the slope of a variable secant through P; the speed at a given instant is the *limit* of the average speed; the difference of the two values of x, Δx, was thought of as *approaching zero;* and so on. To make these concepts clear, the following precise statements are necessary and desirable.

When the difference between a variable x and a constant a becomes and remains less, in absolute value, than any preassigned positive quantity, however small, then a is the* ***limit*** *of the variable x.*

We also use the expression "x approaches a as a limit," or, more simply, "x approaches a." The symbol for limit is *lim;* the symbol for approaches is $\rightarrow$; thus we may write $\lim x = a$, or $x \rightarrow a$, or $\lim (a - x) = 0$, or $a - x \rightarrow 0$.†

When the limit of a variable is *zero*, the variable is called an ***infinitesimal***. Thus $a - x$ above is an infinitesimal. The difference between any variable and its limit is always an infinitesimal. *When a variable x approaches a limit a, any* ***continuous*** *function $f(x)$ approaches the limit $f(a)$*:

* When dealing with real numbers, absolute value is the value without regard to signs, so that the absolute value of -2 is 2, for example. A convenient symbol for it is two vertical lines; thus $|3-7|=4$.

† The symbol $\doteq$ is often used in place of $\rightarrow$.

thus, if $y = f(x)$ and $b = f(a)$, we may write

$$\lim_{x \to a} y = b, \quad \text{or} \quad \lim_{x \to a} f(x) = f(a).$$

This condition is the precise definition of continuity at the point $x = a$. (See § 9, p. 11.)

11. Properties of Limits. The following properties of limits will be assumed as self-evident. Some of them have already been used in the articles noted below.

Theorem A. *The limit of the sum of two variables is the sum of the limits of the two variables.* This is easily extended to the case of more than two variables. (Used in §§ 4, 6, and 7.)

Theorem B. *The limit of the product of two variables is the product of the limits of the variables.* (Used in §§ 4, 6, and 7.)

Theorem C. *The limit of the quotient of one variable divided by another is the quotient of the limits of the variables,* ***provided*** *the limit of the divisor is not zero.* (Used in § 8.)

The exceptional case in Theorem C is really the most interesting and important case of all. The exception arises because when zero occurs as a denominator, the division cannot be performed. In finding the slope of a curve, we consider lim $(\Delta y/\Delta x)$ *as* Δx *approaches zero;* notice that this is precisely the case ruled out in Theorem C. Again, the speed is lim $(\Delta s/\Delta t)$ *as* Δt *approaches zero.* The limit of any such *difference quotient* is one of these exceptional cases.

Theorem D. *The limit of the ratio of two infinitesimals depends upon the law connecting them; otherwise it is quite indeterminate.* Of this the student will see many instances; for *the Differential Calculus consists of the consideration of just such limits.* In fact, the very reason for the existence of the Differ-

ential Calculus is that the exceptional case of Theorem C is important, and cannot be settled in an offhand manner.

The thing to be noted here is, that, no matter how small two quantities may be, their ratio may be either small or large; and that, if the two quantities are variables whose limit is zero, the limit of their ratio may be either finite, zero, or non-existent. In our work with such forms we shall try to substitute an equivalent form whose limit can be found.

Theorem D accounts for the case when the numerator as well as the denominator in Theorem C is infinitesimal. There remains the case when the denominator only is infinitesimal. *A variable whose reciprocal is infinitesimal is said to become infinite as the reciprocal approaches zero.*

Thus

$$y = 1/x$$

is a variable whose reciprocal is x. As x approaches zero, y is said to become infinite. Notice, however, that y has no value whatever when $x = 0$.

Likewise

$$y = \sec x$$

is a variable whose reciprocal, $\cos x$, is infinitesimal as x approaches $\pi/2$. Hence we say that $\sec x$ becomes infinite as x approaches $\pi/2$. In any case, it is clear that a variable which becomes infinite becomes and remains larger in absolute value than any preassigned positive number, however large.

The student should carefully notice that infinity is not a number. When we say that "$\sec x$ becomes infinite as x approaches $\pi/2$," * we do not mean that $\sec(\pi/2)$ has a value, we merely tell what occurs when x approaches $\pi/2$.

* Or, as is stated in short form in many texts, "$\sec(\pi/2) = \infty$."

EXERCISES

1. Imagine a point traversing a line-segment in such fashion that it traverses half the segment in the first second, half the remainder in the next second, and so on; always half the remainder in the next following second. Will it ever traverse the entire line? Show that the remainder after t seconds is $1/2^t$, if the total length of the segment is 1. Is this infinitesimal? Why?

2. Show that the distance traversed by the point in Ex. 1 in t seconds is $1/2 + 1/2^2 + \dots + 1/2^t$. Show that this sum is equal to $1 - 1/2^t$; hence show that its limit is 1. Show that in any case the limit of the distance traversed is the total distance, as t increases indefinitely.

3. Show that the limit of $3 - x^2$ as x approaches zero is 3. State this result in the symbols used in § 10. Draw the graph of $y = 3 - x^2$ and show that y approaches 3 as x approaches zero.

Evaluate the following limits:

4. $\lim\limits_{x \to 0} (7 - 5x + 3x^2)$. **7.** $\lim\limits_{x \to 2} \dfrac{3 - 2x^2}{4 + 2x^2}$. **10.** $\lim\limits_{x \to 2} \dfrac{x^2 - 3x + 2}{x^2 + 2x + 3}$.

5. $\lim\limits_{x \to 2} (7 - 5x + 3x^2)$. **8.** $\lim\limits_{x \to 0} \dfrac{2x}{4 - x}$. **11.** $\lim\limits_{x \to 1} \dfrac{a + bx}{c + dx}$.

6. $\lim\limits_{x \to k} (k^2 + kx - 2x^2)$. **9.** $\lim\limits_{x \to 2} \dfrac{1 - x}{x}$. **12.** $\lim\limits_{x \to 0} \dfrac{a + bx + cx^2}{m + nx + lx^2}$.

If the numerator and denominator of a fraction contain a common factor, that factor may be canceled in finding a limit, since the value of the fraction which we use is not changed. Evaluate before and after canceling a common factor:

13. $\lim\limits_{x \to -1} \dfrac{(x-2)(x-1)}{(2x-3)(x-1)}$. **14.** $\lim\limits_{x \to 2} \dfrac{x^2(x-2)}{(x^2+1)(x-2)}$.

15. $\lim\limits_{x \to 0} \dfrac{x^2}{x}$. **16.** $\lim\limits_{x \to 1} \dfrac{x^2 - 4x + 3}{x^2 - 1}$. **17.** $\lim\limits_{x \to 1} \dfrac{x^2 + x - 2}{2x^2 + x - 3}$.

18. $\lim\limits_{x \to -1} \dfrac{\sqrt{x+1}}{x+1}$. **19.** $\lim\limits_{x \to 0} \dfrac{x^2(x-1)^2}{x^3 - 2x^2}$. **20.** $\lim\limits_{x \to 0} \dfrac{x^n}{x} = \begin{cases} 0, & n > 1, \\ 1, & n = 1. \end{cases}$

21. Show that

$$\lim_{x \to \infty} \frac{3x^2 + 5}{x^2 + 4x + 5} = 3.$$

[HINT. Divide numerator and denominator by x^2; then such terms as $5/x^2$ approach zero as x becomes infinite.]

Evaluate:

22. $\lim\limits_{x\to\infty}\dfrac{2x-1}{3x-2}$. **23.** $\lim\limits_{x\to\infty}\dfrac{5x^2-4}{3x^2+2}$. **24.** $\lim\limits_{x\to\infty}\dfrac{ax+b}{mx+n}$.

25. $\lim\limits_{x\to\infty}\dfrac{2x}{\sqrt{1+x^2}}$. **26.** $\lim\limits_{x\to\infty}\dfrac{\sqrt{1+x^2}}{\sqrt{x^2-4}}$. **27.** $\lim\limits_{x\to\infty}\dfrac{\sqrt{ax^2+bx+c}}{px+q}$.

28. Let O be the center of a circle of radius $r = OB$, and let $\alpha = \angle\ COB$ be an angle at the center (Fig. 6). Let BT be perpendicular to OB, and let BF be perpendicular to OC. Show that OF approaches OC as α approaches zero; likewise arc $CB \to 0$, arc $DB \to 0$, and $FC \to 0$, as $\alpha \to 0$.

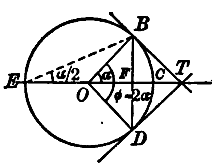

Fig. 6.

29. In Fig. 6, show that the obvious geometric inequality $FB <$ arc $CB < BT$ is equivalent to $r \sin\alpha < r\cdot\alpha < r\tan\alpha$, if α is measured in circular measure. Hence show that $\alpha/\sin\alpha$ lies between 1 and $1/\cos\alpha$, and therefore that $\lim(\alpha/\sin\alpha) = 1$ as $\alpha \to 0$. (Cf. § 72.)

30. In Fig. 6, show that

$$\lim_{\alpha\to 0}\frac{FB}{r} = 0;\ \lim_{\alpha\to 0}\frac{OF}{r} = 1;\ \lim_{\alpha\to 0}\frac{BT}{r} = 0;\ \lim_{\alpha\to 0}\frac{FC}{r} = 0;\ \lim_{\alpha\to 0}\frac{\text{arc } CB}{r} = 0.$$

12. Derivatives. While such illustrations as those in the preceding exercises are interesting and reasonably important, by far the most important cases of the ratio of two infinitesimals are those of the type studied in §§ 4–8, in which each of the infinitesimals is the difference of two values of a variable, such as $\Delta y/\Delta x$ or $\Delta s/\Delta t$. Such a difference quotient $\Delta y/\Delta x$, of y with respect to x, evidently represents the ***average*** rate of increase of y with respect to x in the interval Δx; if x represents time and y distance, then $\Delta y/\Delta x$ is the average speed over the interval Δx (§ 7, p. 9); if $y = f(x)$ is thought of as a curve, then $\Delta y/\Delta x$ is the slope of a secant or the average rate of rise of the curve in the interval Δx (§ 4, p. 4).

The *limit* obtained in such cases represents the ***instantaneous rate of increase*** of one variable with respect to the other, — this may be the slope of a curve, or the speed of a moving object, or some other *rate*, depending upon the nature of the problem in which it arises.

In general, *the limit of the quotient $\Delta y/\Delta x$ of two infinitesimal differences is called* ***the derivative of y with respect to x****; it is represented by the symbol* dy/dx:

$$\frac{dy}{dx} \equiv \textit{derivative of } y \textit{ with respect to } x = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x}.$$

Henceforth we shall use this new symbol dy/dx or other convenient abbreviations; * but the student must not forget the real meaning: *slope*, in the case of curve; *speed*, in the case of motion; some other tangible concept in any new problem which we may undertake. *In every case the meaning is the rate of increase of y with respect to x.*

Any mathematical formulas we obtain will apply in any of these cases. We shall use the letters x and y, the letters s and t, and other suggestive combinations; but any formula written in x and y also holds true, for example, with the letters s and t, or for any other pair of letters.

13. Formula for Derivatives. If we are to find the value of a derivative, as in §§ 4–7, we must have given one of the variables y as a function of the other x:

$$(1) \qquad y = f(x).$$

If we think of (1) as a curve, we may take, as in § 4, any

* Often read "the x derivative of y." Other names frequently used are *differential coefficient* and *derived function*. Other convenient notations are $D_x y$, y_x, $f'(x)$ y', $\dot{y}$; the last two are not safe unless it is otherwise clear what the independent variable is.

point P whose coördinates are x and y, and join it by a secant PQ to any other point Q, whose coördinates are $x + \Delta x, y + \Delta y$.

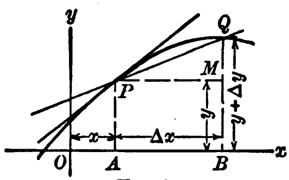

FIG. 7.

Here x and y represent fixed values of x and y. This will prove more convenient than to use new letters each time, as we did in §§ 4–7.

Since P lies on the curve (1), its coördinates (x, y) satisfy the equation (1), $y = f(x)$. Since Q lies on (1), $x + \Delta x$ and $y + \Delta y$ satisfy the same equation; hence we must have

$$(2) \qquad y + \Delta y = f(x + \Delta x).$$

Subtracting (1) from (2) we get

$$(3) \qquad \Delta y = f(x + \Delta x) - f(x).$$

Whence the *difference quotient* is

$$(4) \qquad \frac{\Delta y}{\Delta x} = \frac{f(x + \Delta x) - f(x)}{\Delta x} = \textit{average slope over } PM,$$

and therefore the *derivative* is

$$(5) \qquad \frac{dy}{dx} = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} \equiv \lim_{\Delta x \to 0} \frac{f(x + \Delta x) - f(x)}{\Delta x} = \textit{slope at } P.^*$$

14. Rule for Differentiation. The process of finding a derivative is called ***differentiation***. To apply formula (5) of § 13:

(*A*) *Find* $(y + \Delta y)$ *by substituting* $(x + \Delta x)$ *for* x *in the given function or equation;* this gives $y + \Delta y = f(x + \Delta x)$.

(*B*) *Subtract* y *from* $y + \Delta y$; this gives

$$\Delta y = f(x + \Delta x) - f(x).$$

* Instead of *slope*, read *speed* in case the problem deals with a motion, as in § 7. In general, $\Delta y / \Delta x$ is the *average* rate of increase, and dy/dx is the *instantaneous* rate.

(*C*) *Divide* Δy *by* Δx *to find the difference quotient* $\Delta y/\Delta x$; *simplify this result.*

(*D*) *Find the* ***limit*** *of* $\Delta y/\Delta x$ *as* Δx *approaches zero;* this result is the ***derivative***, dy/dx.

EXAMPLE 1. Given $y = f(x) \equiv x^2$, to find dy/dx.

(*A*) $$f(x + \Delta x) = (x + \Delta x)^2.$$

(*B*) $$\Delta y = f(x + \Delta x) - f(x) = (x + \Delta x)^2 - x^2 = 2\,x\,\Delta x + \overline{\Delta x}^2.$$

(*C*) $$\Delta y/\Delta x = (2\,x\,\Delta x + \overline{\Delta x}^2) \div \Delta x = 2\,x + \Delta x.$$

(*D*) $$dy/dx = \lim_{\Delta x \to 0} \Delta y/\Delta x = \lim_{\Delta x \to 0} (2\,x + \Delta x) = 2\,x.$$

Compare this work and the answer with the work of § 4, p. 5.

EXAMPLE 2. Given $y = f(x) \equiv x^3 - 12\,x + 7$, to find dy/dx.

$$f(x + \Delta x) = (x + \Delta x)^3 - 12\,(x + \Delta x) + 7.$$

(*B*) $$\Delta y = f(x + \Delta x) - f(x) = 3\,x^2\,\Delta x + 3\,x\,\overline{\Delta x}^2 + \overline{\Delta x}^3 - 12\,\Delta x.$$

(*C*) $$\Delta y/\Delta x = 3\,x^2 + 3\,x\,\Delta x + \overline{\Delta x}^2 - 12.$$

(*D*) $$dy/dx = \lim_{\Delta x \to 0} \Delta y/\Delta x = \lim_{\Delta x \to 0} (3\,x^2 + 3\,x\,\Delta x + \overline{\Delta x}^2 - 12) = 3\,x^2 - 12.$$

Compare this work and the answer with the work of Example 3, § 6.

EXAMPLE 3. Given $y = f(x) \equiv 1/x^2$, to find dy/dx.

(*A*) $$f(x + \Delta x) = \frac{1}{(x + \Delta x)^2}.$$

(*B*) $$\Delta y = f(x + \Delta x) - f(x) = \frac{1}{(x + \Delta x)^2} - \frac{1}{x^2} = -\frac{2\,x\,\Delta x + \overline{\Delta x}^2}{x^2\,(x + \Delta x)^2}.$$

(*C*) $$\frac{\Delta y}{\Delta x} = -\frac{2\,x + \Delta x}{x^2\,(x + \Delta x)^2}.$$

(*D*) $$dy/dx = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \to 0} \left[-\frac{2\,x + \Delta x}{x^2\,(x + \Delta x)^2} \right] = -\frac{2\,x}{x^4} = -\frac{2}{x^3}.$$

EXAMPLE 4. Given $y = f(x) \equiv \sqrt{x}$, to find dy/dx, or $df(x)/dx$.

(*A*) $$f(x + \Delta x) = \sqrt{x + \Delta x}.$$

(*B*) $$\Delta y = f(x + \Delta x) - f(x) = \sqrt{x + \Delta x} - \sqrt{x}.$$

(*C*) $$\frac{\Delta y}{\Delta x} = \frac{\sqrt{x + \Delta x} - \sqrt{x}}{\Delta x} = \frac{\sqrt{x + \Delta x} - \sqrt{x}}{\Delta x} \cdot \frac{\sqrt{x + \Delta x} + \sqrt{x}}{\sqrt{x + \Delta x} + \sqrt{x}}$$
$$= \frac{1}{\sqrt{x + \Delta x} + \sqrt{x}}.$$

(*D*) $$\frac{dy}{dx} = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \to 0} \frac{1}{\sqrt{x + \Delta x} + \sqrt{x}} = \frac{1}{2\sqrt{x}}.$$

EXAMPLE 5. Given $y = f(x) \equiv x^7$, to find $df(x)/dx$.

(A) $f(x + \Delta x) = (x + \Delta x)^7 = x^7 + 7x^6 \Delta x +$ (terms with a factor $\overline{\Delta x}^2$).

(B) $\Delta y = f(x + \Delta x) - f(x) = 7x^6 \Delta x +$ (terms with a factor $\overline{\Delta x}^2$).

(C) $\Delta y/\Delta x = 7x^6 +$ (terms with a factor Δx).

(D) $dy/dx = \lim\limits_{\Delta x \to 0} \Delta y/\Delta x = \lim\limits_{\Delta x \to 0} [7x^6 +$ (terms with a factor Δx)$] = 7x^6$.

EXERCISES

Find the derivative, with respect to x, of each of the following functions:

1. $x^2 - 4x + 3$.
2. $x^3 + 2x^2$.
3. $3x - x^3$.
4. $x^4 + 2x^2$.
5. $8x - x^4$.
6. $x^4 + x^2 + 1$.
7. $\dfrac{1}{x-1}$.
8. $\dfrac{2}{4x-3}$.
9. $\dfrac{1}{x^2}$.
10. $\dfrac{x}{x-1}$.
11. $\dfrac{3x-2}{x+2}$.
12. $\sqrt{x-1}$.

13. Find the equation of the tangent to the curve $y = 4/x$ at the point where $x = 3$.

14. Determine the values of x for which the curve $y = x^3 - 12x + 4$ rises, and those for which it falls. Draw the graph accurately.

Proceed as in Ex. 14 for each of the following curves:

15. $x^3 - 15x + 3$.
16. $x^3 - 3x^2$.
17. $2x^4 - 64x$.
18. $x^4 - 32x^2$.

19. If a body moves so that its horizontal and its vertical distances from a point are, respectively, $x = 15t$, $y = -16t^2 + 15t$, find its horizontal speed and its vertical speed. Show that the path is

$$y = -16x^2/225 + x,$$

and that the slope of this path is the ratio of the vertical speed to the horizontal speed. [These equations represent, approximately, the motion of an object thrown upward at an angle of 45°, with a speed $15\sqrt{2}$.]

20. A stone is dropped into still water. The circumference c of the growing circular waves thus made, as a function of the radius r, is $c = 2\pi r$. Show that $dc/dr = 2\pi$, *i.e.* that the circumference changes 2π times as fast as the radius.

Let A be the area of the circle. Show that $dA/dr = 2\pi r$; *i.e.* the rate at which the area is changing compared to the radius is numerically equal to the circumference.

21. Determine the rates of change of the following variables:

(*a*) The surface of a sphere compared with its radius, as the sphere expands.

(*b*) The volume of a cube compared with its edge, as the cube enlarges.

(*c*) The volume of a right circular cone compared with the radius of its base (the height being fixed), as the base spreads out.

22. If a man 6 ft. tall is at a distance x from the base of an arc light 10 ft. high, and if the length of his shadow is s, show that $s/6 = x/4$, or $s = 3x/2$. Find the rate (ds/dx) at which the length s of his shadow increases as compared with his distance x from the lamp base.

CHAPTER III

DIFFERENTIATION OF ALGEBRAIC FUNCTIONS

15. Classification of Functions. For convenience it is usual to classify functions into certain groups.

A function which can be expressed directly in terms of the independent variable x by means of the three elementary operations of multiplication, addition, and subtraction is called a ***polynomial*** in x.

Thus, $2x^3 + 4x^2 - 7x + 3$, $x^3 - 4x + 6$, etc., are polynomials. The most general polynomial is $a_0x^n + a_1x^{n-1} + \ldots + a_{n-1}x + a_n$, where the coefficients $a_0, a_1, \ldots, a_n$ are constants, and the exponents are positive integers.

A function which can be expressed directly in terms of the independent variable x by means of the four elementary operations of multiplication, division, addition, and subtraction, is called a ***rational function*** of x. Thus, $1/x$, $(x^3 - 3x)/(2x+7)$, etc., are rational. The most general rational function is the quotient of two polynomials, since more than one division can be reduced to a single division by the rules for the combination of fractions. All polynomials are also rational functions.

If, besides the four elementary operations, a function requires for its direct expression in the independent variable x at most the extraction of integral roots, it is called a ***simple algebraic function**** of x. Thus, $\sqrt{x}$, $(\sqrt{x^2+1} - 2)/(3 - \sqrt[3]{x})$,

* Since the expression "algebraic function" is used in the broader sense of § 25 in advanced mathematics, we shall call these *simple* algebraic functions.

etc., are simple algebraic functions. All rational functions are also simple algebraic functions.

Simple algebraic functions which are not rational are called ***irrational functions***.

A function which is not an algebraic function is called a ***transcendental function***. Thus $\sin x$, $\log x$, e^x, $\tan^{-1}(1+x)+x^2$, etc., are transcendental.

In this chapter we shall deal only with algebraic functions.

16. Differentiation of Polynomials. We have differentiated a number of polynomials in Chapter I. To simplify the work to a mere matter of routine, we need four rules:

The derivative of a constant is zero:

$$\text{[I]} \qquad \frac{dc}{dx} = 0.$$

The derivative of a constant times a function is equal to the constant times the derivative of the function:

$$\text{[II]} \qquad \frac{d(c \cdot u)}{dx} = c \cdot \frac{du}{dx}.$$

The derivative of the sum of two functions is equal to the sum of their derivatives:

$$\text{[III]} \qquad \frac{d(u+v)}{dx} = \frac{du}{dx} + \frac{dv}{dx}.$$

The derivative of a power, x^n, with respect to x is nx^{n-1}:

$$\text{[IV]} \qquad \frac{dx^n}{dx} = nx^{n-1}.$$

[We shall prove this at once in the case when n is a positive integer; later we shall prove that it is true also for negative and fractional values of n.]

Each of these rules was illustrated in Chapter II, § 14. To prove them we use the rule of § 14.

Proof of [I]. If $y=c$, a change in x produces no change in y; hence $\Delta y = 0$. Therefore $dy/dx = \lim \Delta y/\Delta x = \lim 0 = 0$ as Δx approaches zero. Geometrically, the slope of the curve $y = c$ (a horizontal straight line) is everywhere zero.

Proof of [II]. If $y = c\cdot u$ where u is a function of x, a change Δx in x produces a change Δu in u and a change Δy in y; following the rule of § 14 we find:

$$(A)\qquad y + \Delta y = c\cdot (u + \Delta u).$$

$$(B)\qquad \Delta y = c\cdot \Delta u.$$

$$(C)\qquad \frac{\Delta y}{\Delta x} = c\cdot \frac{\Delta u}{\Delta x}.$$

$$(D)\qquad \frac{dy}{dx} = \lim_{\Delta x \to 0}\left[c\cdot \frac{\Delta u}{\Delta x}\right] = c\cdot \lim_{\Delta x\to 0}\frac{\Delta u}{\Delta x} = c\frac{du}{dx}.$$

Thus $d(7x^2)/dx = 7\cdot d(x^2)/dx = 7\cdot 2\,x = 14\,x$. (See §§ 4, 15.)

Proof of [III]. If $y = u + v$, where u and v are functions of x, a change Δx in x produces changes Δy, Δu, Δv in y, u, v, respectively, hence

$$(A)\qquad y + \Delta y = (u + \Delta u) + (v + \Delta v);$$

$$(B)\qquad \Delta y = \Delta u + \Delta v;$$

$$(C)\qquad \frac{\Delta y}{\Delta x} = \frac{\Delta u}{\Delta x} + \frac{\Delta v}{\Delta x};$$

$$(D)\qquad \frac{dy}{dx} = \lim_{\Delta x\to 0}\frac{\Delta u}{\Delta x} + \lim_{\Delta x\to 0}\frac{\Delta v}{\Delta x} = \frac{du}{dx} + \frac{dv}{dx}.$$

Thus

$$\frac{d(x^3 - 12\,x + 7)}{dx} = \frac{d(x^3)}{dx} - \frac{d(12\,x)}{dx} + \frac{d(7)}{dx} = 3\,x^2 - 12 + 0,$$

by applying the preceding rules and noticing that $dx^3/dx = 3\,x^2$.

Proof of [IV]. If $y = x^n$, we proceed as in Example 5, § 14.

(A) $y + \Delta y = (x + \Delta x)^n = x^n + nx^{n-1}\Delta x +$ (terms which have a common factor $\overline{\Delta x}^2$).

(B) $\Delta y = nx^{n-1}\Delta x +$ (terms with a common factor $\overline{\Delta x}^2$).

(C) $\Delta y/\Delta x = nx^{n-1} +$ (terms which have a factor Δx).

(D) $dy/dx = \lim\limits_{\Delta x \to 0} (\Delta y/\Delta x) = nx^{n-1}$.

This proof holds good only for positive integral values of n. For negative and fractional values of n, see §§ 17, 21.

EXAMPLE 1. $d(x^9)/dx = 9x^8$.

EXAMPLE 2. $dx/dx = 1 \cdot x^0 = 1$, since $x^0 = 1$.
This is also evident directly: $dx/dx = \lim\limits_{\Delta x \to 0} \Delta x/\Delta x = 1$. Notice however that no new rule is necessary.

EXAMPLE 3. $\dfrac{d}{dx}(x^4 - 7x^2 + 3x - 5) = 4x^3 - 14x + 3$.

EXAMPLE 4. $\dfrac{d}{dx}(Ax^m + Bx^n + C) = mAx^{m-1} + nBx^{n-1}$.

EXERCISES

Calculate the derivative of each of the following expressions with respect to the independent variable it contains (x or r or s or t or y or u). In this list, the first letters of the alphabet, down to n, inclusive, represent constants.

1. $y = 3x^4$.
2. $y = x^5/5$.
3. $y = 4x^5 + 5$.
4. $y = 5(x^6 - 3)$.
5. $s = 10t^5 + 50t$.
6. $s = -4t + 2t^3$.
7. $s = 3(t^4 - 2t^2)$.
8. $s = mt^2 + nt^3$.
9. $q = 6t^3 + 3t^6$.
10. $q = t^7 - 8t^5 + 10$.
11. $q = 6(r^3 + r^2 + 1)$.
12. $q = Ar^{10} + Br^5$.
13. $u = v(v - 1)$.
14. $u = (1 - v^2)(2 + v^2)$.
15. $u = v^6(v^5 + 2)$.
16. $u = (v^6 + 2)(v^6 - 3)$.
17. $z = ay^5(y^3 - by^4)$.
18. $z = u^{10}(2u^7 - 5u^9 + 8)$.
19. $z = kx^m + hx^n$.
20. $r = cx^{3n} - dx^{2m}$.
21. $r = t^n(t^{2n} - t^2)$.
22. $t = A - By^{m^2}$.

Locate the vertex of each of the following parabolas by finding the point at which the slope is zero.

23. $y = x^2 + 4x + 4$.

24. $y = x^2 - 6x + 2$.

25. $y = 5 + 2x - x^2$.

26. $y = ax^2 + 2bx + c$.

27. What is the slope of the curve $y = 2x^3 - 3x^2 + 4$ at $x = 0, \pm 2, \pm 4$? Where is the slope $9/2$? $-3/2$? Where is the tangent horizontal? Draw the graph.

28. What is the slope of the curve $y = x^4/4 - 2x^3 + 4x^2$ at $x = 0, 1, -1, -2$? Where is the tangent horizontal? Where is the slope equal to eight times the value of x?

29. Show that the function $x^3 - 3x^2 + 3x - 1$ always increases with x. Where is the tangent horizontal?

30. Find the angle between the curve $y = x^3$ and the straight line $y = 9x$ at each of their points of intersection.

17. Differentiation of Rational Functions. In order to differentiate all rational functions, we need only one more rule, — that for differentiating a *fraction*.

The derivative of a quotient N/D of two functions N and D is equal to the denominator times the derivative of the numerator minus the numerator times the derivative of the denominator, all divided by the square of the denominator:

$$\text{[V]} \qquad \frac{d\left(\frac{N}{D}\right)}{dx} = \frac{D\frac{dN}{dx} - N\frac{dD}{dx}}{D^2}.$$

To prove this rule, let $y = N/D$, where N and D are functions of x; then a change Δx in x produces changes Δy, ΔN, ΔD in y, N, and D, respectively. Hence, by the rule of § 14:

$$(A) \qquad y + \Delta y = \frac{N + \Delta N}{D + \Delta D};$$

$$(B) \qquad \Delta y = \frac{N + \Delta N}{D + \Delta D} - \frac{N}{D} = \frac{D \cdot \Delta N - N \cdot \Delta D}{D(D + \Delta D)};$$

(C) $$\frac{\Delta y}{\Delta x}=\frac{D\dfrac{\Delta N}{\Delta x}-N\dfrac{\Delta D}{\Delta x}}{D(D+\Delta D)};$$

(D) $$\frac{dy}{dx}=\lim_{\Delta x\to 0}\frac{\Delta y}{\Delta x}=\frac{D\dfrac{dN}{dx}-N\dfrac{dD}{dx}}{D^2}.$$

EXAMPLE 1. $$\frac{d}{dx}\left(\frac{x^2+3}{3x-7}\right)=\frac{(3x-7)\dfrac{d}{dx}(x^2+3)-(x^2+3)\dfrac{d}{dx}(3x-7)}{(3x-7)^2}$$
$$=\frac{(3x-7)\cdot 2x-(x^2+3)\cdot 3}{(3x-7)^2}=\frac{3x^2-14x-9}{(3x-7)^2}.$$

EXAMPLE 2. $$\frac{d}{dx}\left(\frac{1}{x^2}\right)=\frac{x^2\dfrac{d1}{dx}-1\cdot\dfrac{d(x^2)}{dx}}{(x^2)^2}=\frac{0-2x}{x^4}=-\frac{2}{x^3}.$$

(Compare Example 3, § 14.)

EXAMPLE 3. $$\frac{d}{dx}(x^{-k})=\frac{d}{dx}\left(\frac{1}{x^k}\right)=\frac{0-kx^{k-1}}{x^{2k}}=\frac{-k}{x^{k+1}}=-kx^{-k-1}.$$

Note that formula IV holds also when n is a negative integer, for if $n=-k$, formula IV gives the result we have just proved.

EXERCISES

Calculate the derivative of each of the following functions.

1. $y=\dfrac{1-x}{x}$.
2. $y=\dfrac{x}{1+x}$.
3. $y=\dfrac{x-2}{x+4}$.
4. $y=\dfrac{3x-4}{x^2+4}$.
5. $y=\dfrac{3}{x^3}$.
6. $y=2x^{-5}\left(=\dfrac{2}{x^5}\right)$.
7. $y=4x^{-7}+\dfrac{2}{x^2}$.
8. $s=\dfrac{3t^5+5}{t^2}$.
9. $s=\dfrac{t^2}{t^3-1}$.
10. $s=ht^5-kt^{-5}$.

11. $v = u^2 - \dfrac{u^4+1}{u^2-1}$.

12. $v = \dfrac{3+6u-5u^2}{u}$.

13. $v = \dfrac{16u^3+4u^2-3u}{3u^2}$.

14. $q = ar^{-m} + br^{-n}$.

15. $q = \dfrac{r^2-r^3}{r^3-r^2}$.

16. $w = \dfrac{az^{-4}}{bz^2+c}$.

17. $w = \dfrac{2}{z^3} + \dfrac{3}{z^2+1}$.

18. $w = \left(z^2 + \dfrac{1}{z}\right) \div \left(1 - \dfrac{1}{z}\right)$.

19. $w = \dfrac{r^2+r+1}{r^2-r+1}$.

20. $z = \dfrac{y^2+2y-3}{y^2-2y+6}$.

21. $x = \dfrac{2y+1}{y^3-1} - \dfrac{5}{y^2+y+1}$.

22. $q = \dfrac{r^4/4+2r^3-6}{2r^2/7}$.

23. $s = (t^{-3}+4)(t^{-3}-5)$.

24. $r = a + b \div \left(u + \dfrac{c}{u}\right)$.

25. $u = v \div \left(v^2 - \dfrac{1}{v^2}\right)$.

26. $u = \dfrac{mv+n}{(bm-an)(av+b)}$

27. $y = \dfrac{2ax+b}{2a^2(ax+b)^2}$.

28. $y = \dfrac{x}{(x^3+3x+1)^2}$.

29. $z = \dfrac{1+3y-3y^2}{3(y-1)^3}$.

30. $z = \dfrac{x^6}{(5-7x^5)^2}$.

31. Compare the slopes of the family of curves $y = x^n$, where $n = 0$, $+1$, $+2$, etc., -1, -2, etc., at the common point (1, 1). What is the angle between $y = x^2$ and $y = x^{-1}$? See *Tables*, III, *A*.

18. Derivative of a Product. The following rule is often useful in simplifying differentiations:

The derivative of the product of two functions is equal to the first factor times the derivative of the second plus the second factor times the derivative of the first:

$$\text{[VI]} \qquad \frac{d(u \cdot v)}{dx} = u \cdot \frac{dv}{dx} + v \cdot \frac{du}{dx}.$$

If $y = u \cdot v$ where u and v are functions of x, a change Δx in x produces changes Δy, Δu, Δv in y, u, and v, respectively:

(A) $y + \Delta y = (u + \Delta u)\,(v + \Delta v)$;

(B) $\Delta y = (u + \Delta u)\,(v + \Delta v) - u \cdot v = u\,\Delta v + v\,\Delta u + \Delta u\,\Delta v$;

(C) $\Delta y/\Delta x = u(\Delta v/\Delta x) + v(\Delta u/\Delta x) + \Delta u \dfrac{\Delta v}{\Delta x}$;

(D) $dy/dx = \lim\limits_{\Delta x \to 0} (\Delta y/\Delta x) = u(dv/dx) + v(du/dx)$.

EXAMPLE 1. To find the derivative of $y = (x^2 + 3)(x^3 + 4)$.

Method 1. We may perform the indicated multiplication and write:

$$\frac{dy}{dx} = \frac{d}{dx}[(x^2 + 3)(x^3 + 4)] = \frac{d}{dx}[x^5 + 3x^3 + 4x^2 + 12] = 5x^4 + 9x^2 + 8x.$$

Method 2. Using the new rule, we write:

$$\begin{aligned}\frac{dy}{dx} &= (x^2 + 3)\frac{d}{dx}(x^3 + 4) + (x^3 + 4)\frac{d}{dx}(x^2 + 3)\\ &= (x^2 + 3)3x^2 + (x^3 + 4)2x = 5x^4 + 9x^2 + 8x.\end{aligned}$$

In other examples which we shall soon meet, the saving in labor due to the new rule is even greater than in this example.

19. The Derivative of a Function of a Function. Another convenient rule is the following:

The derivative of a function of a variable u, which itself is a function of another variable x, is found by multiplying the derivative of the original function with respect to u by the derivative of u with respect to x.

[VII] $$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}.$$

If y is a function of u, and u is a function of x, a change Δx in x produces a change Δu in u; that in turn produces a change Δy in y; hence:

$$\frac{\Delta y}{\Delta x} = \frac{\Delta y}{\Delta u} \cdot \frac{\Delta u}{\Delta x}.$$

Taking limits on both sides, we have formula [VII].

EXAMPLE 1. To find the derivative of $y = (x^2 + 2)^3$.

Method 1. We may expand the cube and write:

$$\frac{dy}{dx} = \frac{d}{dx}[(x^2+2)^3] = \frac{d}{dx}(x^6 + 6\,x^4 + 12\,x^2 + 8) = 6\,x^5 + 24\,x^3 + 24\,x.$$

Method 2. Using the new rule, we may simplify this work: let $u = x^2 + 2$, then $y = (x^2 + 2)^3 = u^3$; rule [VI] gives

$$\frac{dy}{dx} = \frac{dy}{du}\cdot\frac{du}{dx} = \frac{d(u^3)}{du}\cdot\frac{d(x^2+2)}{dx} = 3\,u^2(2\,x)$$
$$= 3(x^2+2)^2\cdot(2\,x) = 3(x^4 + 4\,x^2 + 4)\cdot(2x) = 6x^5 + 24\,x^3 + 24\,x.$$

20. Parameter Forms. If x and y are given as functions of a third variable t, in the form

$$x = f(t), \qquad y = \phi(t),$$

the variable t is called a ***parameter***, and the two given equations are called ***parameter equations***. Elimination of t between these equations would give an equation connecting x and y, from which dy/dx might be found. But it is often desirable to find dy/dx without elimination of t. Since

$$\frac{\Delta y}{\Delta x} = \frac{\Delta y}{\Delta t} \div \frac{\Delta x}{\Delta t}$$

we have, in the limit as Δx approaches zero,

[VII*a*] $$\frac{dy}{dx} = \frac{dy}{dt} \div \frac{dx}{dt}.$$

This formula is essentially the same as the result of § 8, p. 11.

If we replace t by y in [VII a], we obtain the following important special case:

[VII*b*] $$\frac{dy}{dx} = 1 \div \frac{dx}{dy}.$$

EXAMPLE. If $y = t^2 + 2$ and $x = 3\,t + 4$, to find dy/dx.

Method 1. We may solve the equation $x = 3\,t + 4$ for t and substitute this value of t in the first equation:

$$y = \left(\frac{x-4}{3}\right)^2 + 2 = \frac{x^2}{9} - \frac{8}{9}x + \frac{34}{9},$$

$$\frac{dy}{dx} = \frac{2}{9}x - \frac{8}{9} = \frac{2}{9}(3t+4) - \frac{8}{9} = \frac{2t}{3}.$$

Method 2. Using the new rule (with letters as used in § 8, p. 11), we write:

$$\frac{dy}{dx} = \frac{dy}{dt} \div \frac{dx}{dt} = \frac{d(t^2+2)}{dt} \div \frac{d(3t+4)}{dt} = 2t \div 3 = \frac{2}{3}t.$$

EXERCISES

1. $y = 2x(x^2 - 1)$.
2. $y = x^2(x^3 + 3)$.
3. $y = (2x - 3)(x + 3)$.
4. $y = (1 + x)(1 - x + x^2)$.
5. $y = (4 - x^2)(1 + x^3)$.
6. $y = (2x - x^2)(2 - 3x - x^3)$.
7. $y = (x^2 - 1)^2$.
8. $y = (2x^2 + 3)^2$.
9. $y = (x^3 - 2)^2$.
10. $y = (x^3 + 2)^3$.
11. $y = (3x^2 + 5)^4$.
12. $y = (5x^3 - 7)^5$.
13. $s = (1 + 2t - 3t^2)^2$.
14. $s = (t^2 + 3t + 7)^3$.
15. $s = (t^3 - t - 4)^3$.
16. $u = (7 - 5v + 2v^3)^4$.
17. $u = (v^4 + 3v^2 - 2)^4$.
18. $u = (a + bv + cv^2)^5$.
19. $y = \dfrac{1}{(t^3 + 1)^2}$.
20. $y = \dfrac{1}{(t^2 + t + 1)^3}$.
21. $y = \dfrac{x^3 + 3}{(x^2 + 2)^3}$.
22. $y = \dfrac{(2x^2 - 5)^3}{(x^3 + 3)^4}$.
23. $r = (2s^2 - 3)^{-2}$.
24. $r = (1 - s^2 + s^4)^{-3}$.
25. $u = (v^2 + 2)^3(3v - 5)^2$.
26. $u = (v^3 - 2)^2(2v - 1)^3$.
27. $s = t(t^2 + 3)(t^3 + 4)$.
28. $s = (1 - t)(1 - 5t^2)(3 - 4t^3)$.

Determine dy/dx in each of the following pairs of equations:

29. $\begin{cases} y = 4u - 6u^2, \\ u = 3x - 4. \end{cases}$

30. $\begin{cases} y = 6u^2 - 7u - 1, \\ u = x^2 - 1/2. \end{cases}$

31. $\begin{cases} y = \dfrac{6z - 4z^3}{5z^2}, \\ z = 2 - 4x. \end{cases}$

32. $\begin{cases} y = \dfrac{1 - z}{z}, \\ z = \dfrac{1 - x}{1 + x}. \end{cases}$

Draw each of the curves represented by the following pairs of parameter equations and determine dy/dx.

33. $\begin{cases} x = t^2, \\ y = 3t + 2. \end{cases}$ **34.** $\begin{cases} x = 2t + 3t^2, \\ y = 2t + 4. \end{cases}$

What is the slope in each case when $t = 1$? Show this in your graphs. Find the value of the slope in each case at a point where the parameter has the value 2.

35. Draw the graph of the function $y = (2x - 1)^2(3x + 4)^2$. Determine its horizontal tangents.

36. Proceed as in Ex. 35, for the function

$$y = (2x - 1)^2 \div (3x + 4)^2.$$

21. Differentiation of Irrational Functions. In order to differentiate irrational expressions, we proceed to prove that the formula for the derivative of a power (Rule [IV]) holds true for all fractional powers:

$$\text{[IV}a\text{]} \qquad \frac{dx^n}{dx} = nx^{n-1}, \quad n = \pm \frac{p}{q},$$

where n is any positive or negative integer or fraction.

The formula has been proved in § 17 for the case when n is a negative integer. Suppose next that

$$(1) \qquad y = x^{p/q},$$

where p and q are any positive or negative integers. If we set

$$(2) \qquad x = t^q, \qquad y = t^p,$$

which together are equivalent to $y = x^{p/q}$, and apply formula [VIIa], we find:

$$\frac{dy}{dx} = \frac{dy}{dt} \div \frac{dx}{dt} = pt^{p-1} \div qt^{q-1} = \frac{p}{q}t^{p-q};$$

but since $t = x^{1/q}$, substitution for t gives

$$\frac{dy}{dx} = \frac{p}{q}(x^{1/q})^{p-q} = \frac{p}{q}x^{p/q-1}.$$

This proves [IV] for all fractional values of n.

The rule also holds when n is incommensurable; for example, given $y = x^{\sqrt{2}}$, it is true that $dy/dx = \sqrt{2}\, x^{\sqrt{2}-1}$; we shall postpone the proof of this until § 85, p. 85.

22. Collection of Formulas. Any formula may be combined with [VII], for in any example, any convenient part may be denoted by a new letter, as in § 20. For example, Rule [IV] may be written

$$\frac{du^n}{dx} = \frac{du^n}{du} \cdot \frac{du}{dx}, \text{ by [VII]}, \qquad = nu^{n-1} \cdot \frac{du}{dx}, \text{ by [IV]}.$$

The formulas we have proved are collected below:

[I] $$\frac{dc}{dx} = 0.$$

[II] $$\frac{d(c \cdot u)}{dx} = c \cdot \frac{du}{dx}.$$

[III] $$\frac{d(u+v)}{dx} = \frac{du}{dx} + \frac{dv}{dx}.$$ Holds for subtraction also.

[IV] $$\frac{du^n}{dx} = nu^{n-1}\frac{du}{dx}.$$

[V] $$\frac{d\left(\frac{N}{D}\right)}{dx} = \frac{D\frac{dN}{dx} - N\frac{dD}{dx}}{D^2}.$$ Special case $\dfrac{d\frac{c}{u}}{dx} = \dfrac{-c\frac{du}{dx}}{u^2}$.

[VI] $$\frac{d(u \cdot v)}{dx} = u\frac{dv}{dx} + v\frac{du}{dx}.$$

[VII] $$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}. \quad [y = f(u),\ u = \phi(x)].$$

[VIIa] $$\frac{dy}{dx} = \frac{dy}{dt} \div \frac{dx}{dt}. \quad [y = f(t),\ x = \phi(t)].$$

[VIIb] $$\frac{dy}{dx} = 1 \div \frac{dx}{dy}.$$

These formulas enable us to differentiate any simple algebraic function.

23. Illustrative Examples of Irrational Functions. In this article the preceding formulas are applied to examples.

EXAMPLE 1. $\dfrac{d\sqrt{x}}{dx} = \dfrac{dx^{1/2}}{dx} = \dfrac{1}{2}x^{1/2-1} = \dfrac{1}{2}x^{-1/2} = \dfrac{1}{2\sqrt{x}}.$

(See Ex. 4, p. 21.)

EXAMPLE 2. Given $y = \sqrt{3x^2+4}$, to find dy/dx.

Method 1. Set $u = 3x^2 + 4$, then $y = \sqrt{u}$; by Rule [VII],

$$\frac{dy}{dx} = \frac{dy}{du}\cdot\frac{du}{dx} = \frac{1}{2\sqrt{u}}\cdot 6x = \frac{6x}{2\sqrt{3x^2+4}} = \frac{3x\sqrt{3x^2+4}}{3x^2+4}.$$

Method 2. Square both sides, and take the derivative of each side of the resulting equation with respect to x:

$$\frac{d(y^2)}{dx} = \frac{d(3x^2+4)}{dx} = 6x.$$

But by Rule [IV],

$$\frac{d(y^2)}{dx} = \frac{d(y^2)}{dy}\cdot\frac{dy}{dx} = 2y\frac{dy}{dx},$$

hence,

$$2y\frac{dy}{dx} = 6x, \text{ or } \frac{dy}{dx} = \frac{3x}{y} = \frac{3x}{\sqrt{3x^2+4}} = \frac{3x\sqrt{3x^2+4}}{3x^2+4}.$$

This method, which is excellent when it can be applied, can be used to give a third proof of the Rule [IV] for fractional powers. The next example is one in which this method cannot be applied directly.

EXAMPLE 3. Given $y = x^3 - 2\sqrt{3x^2+4}$, to find dy/dx.

$$\frac{dy}{dx} = \frac{d(x^3)}{dx} - 2\frac{d}{dx}\sqrt{3x^2+4} = 3x^2 - \frac{6x\sqrt{3x^2+4}}{3x^2+4}.$$

EXAMPLE 4. Given $y = (x^3-2)\sqrt{3x^2+4}$, to find dy/dx.

$$\frac{dy}{dx} = \sqrt{3x^2+4}\,\frac{d}{dx}(x^3-2) + (x^3-2)\frac{d}{dx}(\sqrt{3x^2+4}) \qquad \text{[by Rule VI]}$$

$$= \sqrt{3x^2+4}\cdot 3x^2 + (x^3-2)\frac{3x\sqrt{3x^2+4}}{3x^2+4} \qquad \text{[by Example 2]}$$

$$= \sqrt{3x^2+4}\left[3x^2 + (x^3-2)\cdot\frac{3x}{3x^2+4}\right] = \sqrt{3x^2+4}\cdot\frac{12x^4+12x^2-6x}{3x^2+4}.$$

EXAMPLE 5. Given $y = \dfrac{\sqrt{x+1} - \sqrt{x}}{\sqrt{x+1} + \sqrt{x}}$, to find dy/dx.

First reduce y to its simplest form:

$$y = \frac{\sqrt{x+1} - \sqrt{x}}{\sqrt{x+1} + \sqrt{x}} \cdot \frac{\sqrt{x+1} - \sqrt{x}}{\sqrt{x+1} - \sqrt{x}} = \frac{2\,x + 1 - 2\sqrt{x^2 + x}}{(x+1) - x}$$
$$= 2\,x + 1 - 2\sqrt{x^2 + x}.$$

Then

$$\frac{dy}{dx} = \frac{d}{dx}(2\,x + 1) - 2\frac{d}{dx}\sqrt{x^2 + x} = 2 - 2\frac{d\sqrt{u}}{du}\frac{du}{dx},$$

where $u = x^2 + x$; hence

$$\frac{dy}{dx} = 2 - 2\frac{1}{2\sqrt{u}}\frac{du}{dx} = 2 - \frac{1}{\sqrt{x^2 + x}}(2\,x + 1).$$

This example may be done also by first applying the rule for the derivative of a fraction [Rule V]; but the work is usually simpler, as in this example, if the given expression is first simplified.

EXERCISES

Calculate the derivatives of

1. $y = x^{4/3}$.
2. $s = 10\,t^{5/2}$.
3. $s = 2\sqrt[3]{x^2}$.
4. $v = \frac{4}{5}\sqrt[5]{u^4}$.
5. $y = \sqrt{x\sqrt{x}}$.
6. $s = 7\,t^{-3/4}$.
7. $y = x^2\dfrac{5}{\sqrt{x^6}} - \dfrac{10\,x^3}{\sqrt{x^5}}$.
8. $v = \dfrac{6}{u^4} - \dfrac{2}{\sqrt[3]{u}}$.
9. $s = t^3(2\,t^{2/3} + 3\,t^{-2/3})$.
10. $y = 2\sqrt[3]{x}(x^{1/3} + x^{5/3})$.
11. $y = \dfrac{2}{x^3} - \dfrac{x\sqrt{x^3}}{5} + \sqrt[3]{x^2}$.
12. $s = t^3\left(\dfrac{2}{11}t^2\sqrt{t} - \dfrac{72}{23}\dfrac{t}{\sqrt[6]{t}} + \dfrac{16}{3}\right)$.
13. $y = \sqrt{2 + 3\,x}$.
14. $s = \sqrt{3\,t - 4}$.
15. $v = u\sqrt{2 + 3\,u}$.
16. $s = \sqrt{t^2 - 1}$.
17. $s = \sqrt{t^2 - 3\,t}$.
18. $s = \dfrac{5 + 3\,t}{\sqrt{6\,t - 5}}$.
19. $y = \sqrt[3]{1 + x^2}$.
20. $y = \sqrt[4]{2\,x^3 + 4\,x}$.

21. $y = x^2\sqrt{3x-4}$.

22. $y = (5+3x)\sqrt{6x-4}$.

23. $v = \sqrt{1-x+x^2}$.

24. $s = \dfrac{\sqrt{6t-5}}{5+3t}$.

25. $y = \sqrt{1+\sqrt{x}}$.

26. $s = \sqrt{\dfrac{1-t^2}{1+t^2}}$.

27. $v = \dfrac{\sqrt{a^2-u}}{u}$.

28. $y = (9-6x+5x^2)\sqrt[3]{(1+x^4)^2}$.

29. $s = (1+t^2)\sqrt{1-t^2}$.

30. $y = \dfrac{\sqrt{1+x}-\sqrt{1-x}}{\sqrt{1+x}+\sqrt{1-x}}$.
(First rationalize the denominator.)

31. $y = \dfrac{\sqrt{1+x^2}+x}{\sqrt{1+x^2}-x}$.

32. $y = \dfrac{\sqrt{a^2-x^2}}{\sqrt{a^2+x^2}}$.

Draw the graphs of the equations below, and determine the tangent at the point mentioned in each case.

33. $y = \sqrt{1-x^2}$, $(x = \frac{3}{5})$.

34. $y = \sqrt{1+x^2}$, $(x = \frac{4}{3})$.

35. $y = \sqrt{x}$, $(x = 2)$.

36. $y = \sqrt{(1+x)(2+3x)}$, $(x = 2)$.

37. $y = x\sqrt{1+x}$, $(x = 1)$.

38. $y = x^{1/2} - x^{1/3}$, $(x = 1)$.

39. Find the angle between the curves $y = x^{2/3}$ and $y = x^{3/2}$ at (1, 1).

40. Find the angle between the curves $y = x^{p/q}$ and $y = x^{q/p}$ at (1, 1).

41. In compressing air, if no heat escapes, the pressure and volume of the gas are connected by the relation $pv^{1.41} = \text{const}$. Find the rate of change of the pressure with respect to the volume, dp/dv.

42. In compressing air, if the temperature of the air is constant, the pressure and the volume are connected by the relation $pv = \text{const}$. Find dp/dv, and compare this result with that of Ex. 41.

CHAPTER IV

IMPLICIT FUNCTIONS — DIFFERENTIALS

24. Equations in Unsolved Form. An equation in two variables x and y is often given in unsolved form; *i.e.* neither variable is expressed directly in terms of the other. Thus

$$(1) \qquad x^2 + y^2 = 1$$

represents a circle of unit radius about the origin.

Such an equation often can be solved for one variable in terms of the other; thus (1) gives

$$(2) \qquad y = \sqrt{1 - x^2}, \text{ or } y = -\sqrt{1 - x^2}.$$

The first solution represents the upper half of the circle, the second the lower half. Now we can find dy/dx as in § 23:

$$(3) \qquad \frac{dy}{dx} = \frac{-x}{\sqrt{1 - x^2}}, \text{ or } \frac{dy}{dx} = \frac{+x}{\sqrt{1 - x^2}},$$

where the first holds true on the upper half, the second on the lower half, of the circle.

By Rule [VII] such a derivative may be found directly *without solving* the equation. From (1)

$$\frac{d}{dx}(x^2 + y^2) = \frac{d1}{dx} = 0;$$

but $\dfrac{d}{dx}(x^2 + y^2) = \dfrac{d(x^2)}{dx} + \dfrac{d(y^2)}{dx} = 2x + \dfrac{d(y^2)}{dy} \cdot \dfrac{dy}{dx}$, by VII;

hence

$$(4) \qquad 2x + 2y\frac{dy}{dx} = 0,$$

or

$$\frac{dy}{dx} = -\frac{x}{y}. \tag{5}$$

This result agrees with (3), since $y = \pm\sqrt{1 - x^2}$.

This method is the same as that used in the second solution of Ex. 2, p. 36. It may be used whenever the given equation really has any solution, without actually getting that solution.

Such a formula as (4) is much more convenient than (3), since it is more compact, and is stated in one formula instead of in two. But the student must never use (5) for values of x and y without substituting those values in (1) to make sure that the point (x, y) actually lies on the curve; and he must never use (5) when (5) does not give a definite value for dy/dx.* Thus it would be very unwise to use (4) at the point $x=1$, $y=2$, for that point does not lie on the curve (1); it would be equally unwise to try to substitute $x = 1$, $y = 0$, since that would lead to a division by zero, which is impossible.

25. Explicit and Implicit Functions. If one variable y is expressed directly in terms of another variable x, we say that y is an ***explicit*** function of x.

If, as in § 24, the two variables are related to each other by means of an equation which is not solved explicitly for y, then y is called an ***implicit*** function of x. Thus, (1) in § 24 gives y as an implicit function of x; but either part of (2) gives y as an explicit function of x.

Definition. If the original equation is a simple polynomial

* These precautions, which are quite easy to remember, are really sufficient to avoid all errors for all curves mentioned in this book, at least provided the equation like (4) [not (5)] is used in its original form, before any cancelation has been performed.

in x and y equated to zero, any explicit function of x obtained by solving it for y is called an ***algebraic function.*** See § 15.

EXAMPLE. $x^3 + y^3 - 3xy = 0$. (Folium of Descartes: *Tables*, III, I_5.)

This equation is difficult to solve directly for y. Hence, as in § 24, we find dy/dx by Rule [VII]; differentiating both sides with respect to x, we find:

$$3x^2 + 3y^2\frac{dy}{dx} - 3y - 3x\frac{dy}{dx} = 0;$$

whence
$$\frac{dy}{dx} = \frac{y - x^2}{y^2 - x}.$$

At the point (2/3, 4/3), for example, $dy/dx = 4/5$; hence the equation of the tangent at (2/3, 4/3) is $(y - 4/3) = (4/5)(x - 2/3)$ or $4x - 5y + 4 = 0$. Verify the fact that the point (2/3, 4/3) really lies on the curve. Note that this formula is useless at the point (0, 0) although that point lies on the curve.

EXERCISES

In each of these exercises the student should take some point on the curve, and find the equation of the tangent there.

1. From the equation $x^2y = 1$ find dy/dx by the two methods of § 24, first solving for y, then without solving for y. Write the result in terms of x and y; and also in terms of x alone, when possible.

Find dy/dx in the following examples by the two methods of § 24.

2. $x^3y = 10$.

3. $x^2 - xy = 5$.

4. $2xy + x + y = 0$.

5. $x^2 - 4y^2 = 36$.

6. $x^3 - y^3 = 1$.

7. $x^3 + y^3 = a^3$.

8. $x^4 - 4y^2 = 4$.

9. $x^3 + y^2 - 3x = 0$.

10. $(x + y)^2 - 2x = 4$.

11. $xy^2 - x^2 + y^2 = 0$.

Find dy/dx in the following examples without solving for y: check the answers when possible by the other method of § 24.

12. $x^2 + 2xy + y^2 = 2$.

13. $x^2y^2 - 8xy + 7 = 0$.

14. $ax^2 + 2bxy + cy^2 + 2dx + 2ey + f = 0$.

15. $ax^2 + 2hxy + by^2 = k$.

16. $y^4 - 2y^2x + x^2 = 0$.

17. $\sqrt{x} + \sqrt{y} = \sqrt{a}$.

18. $x^{3/2} + y^{3/2} = a^{3/2}$.

In the following pairs of parameter equations, find dy/dx by § 20: when possible eliminate t to find the ordinary equation, and show that the derivative found is correct. Regarding each pair of equations as defining the position of a point (x, y) at the time t, find the horizontal speed and the vertical speed at the time t. (See § 8.) Find also the total speed from the relation

$$\textit{total speed} = \sqrt{(\textit{horizontal speed})^2 + (\textit{vertical speed})^2}.$$

19. $\begin{cases} x = 4\,t, \\ y = 8\,t^2. \end{cases}$ **20.** $\begin{cases} x = 3\,t + 5, \\ y = 4\,t - 2. \end{cases}$ **21.** $\begin{cases} x = 3\,t^2 + 1, \\ y = 2\,t^3. \end{cases}$

22. $\begin{cases} x = \dfrac{3\,t}{1 + t^3}, \\ y = \dfrac{3\,t^2}{1 + t^3}. \end{cases}$ **23.** $\begin{cases} x = \dfrac{t^2 - 1}{t^2 + 1}, \\ y = \dfrac{-2\,t}{t^2 + 1}. \end{cases}$ **24.** $\begin{cases} x = \dfrac{t^2 + 1}{t^2 - 1}, \\ y = \dfrac{2\,t}{t^2 - 1}. \end{cases}$

25. On a circle of unit radius about the origin $dy/dx = -x/y$; this is positive when x and y have different signs, negative when x and y have the same sign. Show that this agrees with the fact that the circle rises in the second and fourth quadrants and falls in the first and third quadrants as x increases.

26. Show that the curve $xy = 1$ is falling at all its points.

27. Show that the curve $x^2y = 1$ is rising in the second quadrant and falling in the first quadrant.

28. The equation $x^{1/2} + y^{1/2} = 1$ is the equivalent of the equation $x^2 - 2\,xy + y^2 - 2\,x - 2\,y + 1 = 0$, if the radicals $x^{1/2}$ and $y^{1/2}$ be taken with both signs. Show that the values of dy/dx calculated from the two equations agree. By methods of analytic geometry, it is easy to see that the curve is a parabola whose axis is the line $y = x$, with its vertex at $(1/4, 1/4)$.

29. The curve of Ex. 28 is also represented by the parameter equations $4\,x = (1 + t)^2$, $4\,y = (1 - t)^2$. Test this fact by substitution, and show that the value of dy/dx obtained from these equations agrees with the value obtained in Ex. 28. [The curve is most easily drawn from the parameter equations.]

If t denotes the time in seconds since a particle moving on this curve passed the point $(1/4, 1/4)$, find the total speed of the particle at any time.

26. Differentials. Let the curve PQ (Fig. 8) be a part of the graph of the equation $y = f(x)$. Let P be any point (x, y) on the curve, and let Q be a second point $(x + \Delta x, y + \Delta y)$ on it. The change $\Delta x = PM$ in x causes a change $\Delta y = MQ$ in y.

The slope of the tangent PT at the point P is given by the formula

(1) $$m = \tan \alpha = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \frac{dy}{dx}.$$

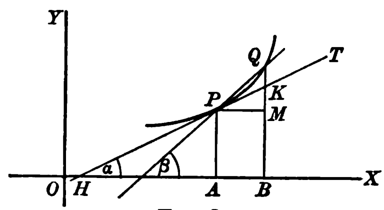

FIG. 8.

If this slope were maintained over the interval Δx, the change produced in y would be

(2) $$MK = m \cdot \Delta x.$$

When Δx is small, the change in y, MQ, will usually be nearly equal to MK. In many problems, it is a sufficiently exact approximation to Δy. Moreover, its value may be found readily by (2), whereas the actual calculation of Δy itself might be tedious or impracticable.

*This quantity MK, which is an approximation to Δy, is called the **differential** of y,* and is denoted by the symbol dy. Hence we may write

(3) $$dy = m \cdot \Delta x = \frac{dy}{dx} \cdot \Delta x.$$

In particular, if the curve is the straight line $y = x$, we find $m = 1$; hence the differential of x is

(4) $$dx = 1 \cdot \Delta x.$$

If we divide (3) by (4) we find

(5) $$dy \div dx = m,$$

where $dy \div dx$ now denotes a real division, since dy and dx

are actual quantities defined by the equations (3) and (4), and dx ($= \Delta x$) is not zero.

Since m stands for the derivative of y with respect to x, it follows that that derivative is equal to the quotient of dy by dx,

$$\frac{dy}{dx} = dy \div dx; \tag{6}$$

this fact is the reason for our use of the symbol dy/dx to represent a derivative originally.

In the figure all quantities here mentioned are shown:

$$dx = \Delta x = AB,\ dy = MK,\ \Delta y = MQ, \frac{\Delta y}{\Delta x} = \tan\beta, \frac{dy}{dx} = \tan\alpha.$$

The quantities $dx\,(= \Delta x)$, $dy\,(= m\Delta x)$, Δy, $\Delta y - dy\,(= KQ)$, are infinitesimal when Δx approaches zero, *i.e.* they approach zero as Δx approaches zero.

27. Differential Formulas. *For any given function $y = f(x)$, dy can be computed in terms of $dx(= \Delta x)$, by computing the derivative and multiplying it by dx.*

Every formula for differentiation can therefore be written as a ***differential formula***; the first six in the list in § 22, p. 35, become after multiplication by dx:

[I] $\quad dc = 0.$ (The differential of a constant is zero.)

[II] $\quad d\,(c \cdot u) = c \cdot du.$

[III] $\quad d\,(u + v) = du + dv.$

[IV] $\quad d\,(u^n) = nu^{n-1}du.$

[V] $\quad d\left(\frac{N}{D}\right) = \frac{DdN - NdD}{D^2}.$

[VI] $\quad d\,(u \cdot v) = u\,dv + v\,du.$

Rules [VII], [VII*a*], and [VII*b*], of § 22, p. 35, appear as identities, since the derivatives may actually be used as quotients of the differentials. From the point of view of the differential notation Rule [VII] merely shows that we may use algebraic cancelation in products or quotients which contain differentials.

Rules [I]–[VI] are sufficient to express all differentials of simple algebraic functions. A great advantage occurs in the case of equations not in explicit form, since all applications of Rule [VII] reduce to algebraic cancelation of differentials.

EXAMPLE 1. Given $y = x^3 - 12x + 7$, to find dy and m.

$$dy = d(x^3 - 12x + 7) = d(x^3) - d(12x) + d(7) = 3x^2 dx - 12 dx,$$

whence $m = dy \div dx = 3x^2 - 12$ as in Example 2, p. 21.

EXAMPLE 2. Given $y = \dfrac{x^2+3}{3x-7}$, to find dy (Example 1, p. 29).

$$\begin{aligned} dy &= \frac{(3x-7)\,d(x^2+3) - (x^2+3)\,d(3x-7)}{(3x-7)^2} \\ &= \frac{3x^2 - 14x - 9}{(3x-7)^2}\,dx. \end{aligned}$$

EXAMPLE 3. Given $y = (x^2+2)^3$, to find dy (Example 1, p. 32).

$$\begin{aligned} dy &= d[(x^2+2)^3] = 3(x^2+2)^2\,d(x^2+2) \\ &= 3(x^2+2)^2 \cdot 2x \cdot dx. \end{aligned}$$

EXAMPLE 4. Given $y = x^3 - 2\sqrt{3x^2+4}$, to find dy (Example 3 p. 36).

$$\begin{aligned} dy &= d(x^3) - 2\,d\sqrt{3x^2+4} \\ &= 3x^2 dx - 2\frac{1}{2\sqrt{3x^2+4}} \cdot d(3x^2+4) \\ &= \left(3x^2 - \frac{1}{\sqrt{3x^2+4}}6x\right)dx. \end{aligned}$$

EXAMPLE 5. Given $x^2 + y^2 = 1$, to find dy in terms of dx (§ 24, p. 39).

$$\begin{aligned} d(x^2+y^2) = d(1) = 0; \text{ but } d(x^2+y^2) &= d(x^2) + d(y^2) \\ &= 2x\,dx + 2y\,dy; \end{aligned}$$

hence $2x\,dx + 2y\,dy = 0$, or $dy = -(x/y)\,dx$, or $m = dy/dx = -x/y$.

EXAMPLE 6. To find dy and m when $x^3 + y^3 - 3xy = 0$. (Example, p. 41.)

$$d(x^3) + d(y^3) - 3\,d(xy) = 0,$$

or

$$3x^2\,dx + 3y^2\,dy - 3x\,dy - 3y\,dx = 0,$$

or

$$(x^2 - y)\,dx + (y^2 - x)\,dy = 0,$$

whence

$$dy = \frac{y - x^2}{y^2 - x}\,dx, \text{ or } m = \frac{dy}{dx} = \frac{y - x^2}{y^2 - x}.$$

EXAMPLE 7. To find dy in terms of dx when $x = 3t + 4$, $y = t^2 + 2$. (Example, p. 32.)

We find $\quad dx = d(3t + 4) = 3\,dt;\ dy = d(t^2 + 2) = 2t\,dt;$

hence $\quad m = dy \div dx = (2/3)\,t$, or $dy = (2/3)\,t\,dx;$

but since $t = (x - 4)/3$, this may be written:

$$dy = (2/9)(x - 4)\,dx, \text{ or } m = \frac{dy}{dx} = (2/9)(x - 4).$$

EXERCISES

[These exercises may be used for further drill in differentiation, and for reviews. It is scarcely advisable that all of them should be solved on first reading.]

Calculate the differentials of the following expressions.

1. $y = ax^2 + bx + c.$
2. $y = (a^2 + x^2)^2.$
3. $y = (ax^2 + bx + c)^3.$
4. $y = (a - bx^2)^5.$
5. $y = 1/(ax + b).$
6. $y = 1/(ax + b)^2.$
7. $s = (1 + 2t)(1 - 3t).$
8. $s = (2 - 3t)^2(3 + 2t^2).$
9. $s = t^2(a - t)^3.$
10. $s = t^4(3 - 2t^3)^2$
11. $s = \sqrt{3t - t^2}.$
12. $s = \sqrt{t^4 - 1}.$
13. $s = \sqrt{(t^3 - 3t)^3}.$
14. $s = \sqrt[3]{(2t^2 + 1)^2}.$
15. $u = 1/\sqrt{2v + v^2}.$
16. $u = (1 - 2v^2)/(2 - v^2).$
17. $u = \dfrac{v^2 + 2v + 1}{v^3 - 1}.$
18. $u = \dfrac{v^2 - 2v + 3}{v^2 + 2v + 3}.$
19. $z = 1/\sqrt[3]{(2 - y^3)^4}.$
20. $z = 1/\sqrt[4]{(y - a)^3}.$
21. $z = y/\sqrt{1 + y}.$
22. $z = \sqrt{a + by}/y.$
23. $r = (a + bs^n)^p.$
24. $r = \sqrt[p]{a + bs^n}.$
25. $r = 1/(a + bs^n)^p.$
26. $r = 1/\sqrt[p]{a + bs^n}.$
27. $y = \dfrac{1 + \sqrt{x}}{1 - \sqrt{x}}.$
28. $y = \sqrt{\dfrac{a + bx}{a - bx}}.$

Determine dy in terms of dx from the equations below.

29. $xy - y = 4.$

30. $x^2 - 2xy - 3y^2 = 0.$

31. $\dfrac{x^2 + y^2}{x^2 - y^2} = x^2.$

32. $y^4 - 2y^2x - 1 = 0.$

33. $(1 - ax)(x^2 + y^2) = 4.$

34. $x^2 + y^2 = (ax + b)^2.$

35. $\dfrac{y^2}{x^2} = \dfrac{a + bx}{a - bx}.$

36. $(x + y)^{3/2} + (x - y)^{3/2} = a^{3/2}.$

37. Obtain the equation of the tangent at $(2, -1)$ to the curve

$$4x^2 - 2xy - 5y^2 - 6x - 4y - 7 = 0.$$

38. Obtain the equation of the tangent at $(2, 1)$ to the curve

$$x^3 - 7x^2y - 5y^3 + 4x^2 - 10xy + 8x - 5y + 18 = 0.$$

Obtain the equation of the tangent at (x_0, y_0) to each of the following curves:

	Curve	Tangent
39.	$y^2 = 4ax;$	$yy_0 = 2a(x + x_0).$
40.	$x^2 + y^2 = a^2;$	$xx_0 + yy_0 = a^2.$
41.	$\dfrac{x^2}{a^2} \pm \dfrac{y^2}{b^2} = 1;$	$\dfrac{xx_0}{a^2} \pm \dfrac{yy_0}{b^2} = 1.$

Find the derivative dy/dx for the curves defined by each of the pairs of parameter equations given below.

42. $\begin{cases} x = \dfrac{2t}{1 + t}, \\ y = \dfrac{1 - t}{1 + t}. \end{cases}$

43. $\begin{cases} x = \dfrac{2}{3}\sqrt{2t^3}, \\ y = \dfrac{1}{2}t^2. \end{cases}$

44. $\begin{cases} x = \dfrac{3a - 2t}{at}, \\ y = \dfrac{4(a - t)^3}{a^2t^2}. \end{cases}$

45. $\begin{cases} x = \dfrac{\theta}{1 + \theta}, \\ y = \theta^{-1} + \theta^{-2}. \end{cases}$

46. $\begin{cases} x = 4\pi r^2, \\ y = \dfrac{4}{3}\pi r^3. \end{cases}$

47. $\begin{cases} x = \dfrac{1}{4\pi r^2}, \\ y = \dfrac{3}{4\pi r^3} \end{cases}$

48. Calculate the x and y components of the speed (v_x and v_y) at any time t, and the resultant speed $\sqrt{v_x^2 + v_y^2}$, for the motion

$$x = \frac{2t}{1 + t^2}, \quad y = \frac{1 - t^2}{1 + t^2}.$$

49. If a particle moves so that its coördinates in terms of time are

$$x = 1 - t + t^2, \quad y = 1 + t + t^2,$$

show that its path is a parabola. Show that from the moment $t = 0$ its speed steadily increases.

50. The electrical resistance of a platinum wire varies with the temperature, according to the equation

$$R = R_0\,(1 - a\theta + b\theta^2)^{-1};$$

calculate dR in terms of $d\theta$. What is the meaning of $dR/d\theta$?

51. Van der Waal's equation giving the relation between the pressure and volume of a gas at constant temperature is

$$\left(p + \frac{a}{v^2}\right)(v - b) = c.$$

Draw the graph when $a = .0087$, $b = .0023$, $c = 1.1$. Express dv in terms of dp. What is the meaning of dv/dp?

52. The crushing strength of a hollow cast iron column of length l, inner diameter d, and outer diameter D, is

$$T = 46.65\left(\frac{D^{3.55} - d^{3.55}}{l^{1.7}}\right)$$

Calculate the rate of change of T with respect to D, d, and l, when each of these alone varies.

CHAPTER V

TANGENTS — EXTREMES

28. Tangents and Normals. We have seen in § 4, p. 4, that if the equation of a curve C is given in explicit form:

(1) $$y = f(x),$$

the derivative at any point P on C represents the *rate of rise*, or *slope*, of C at P:

(2) $$\left[\frac{dy}{dx}\right]_{\text{at } P} = [\textit{slope of } C]_{\text{at } P} = \textit{slope of } PT = \tan\alpha = m_P,$$

where α is the angle XHT, counted from the positive direction of the X-axis to the tangent PT, and where m_P denotes the slope of C at P.

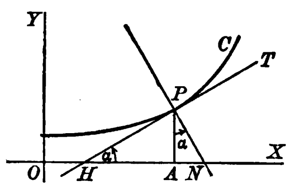

Fig. 9.

Hence (§ 4, p. 5) the *equation of the tangent* is

(3) $$(y - y_P) = \left[\frac{dy}{dx}\right]_P (x - x_P),$$

where the subscript P indicates that the quantity affected is taken with the value which it has at P.

If the slope m_P is *positive*, the curve is *rising* at P; if m_P is *negative*, the curve is *falling;* if m_P is zero, *the tangent is horizontal* (§ 6, p. 6). Points where the slope has any desired value can be found by setting the derivative equal to the given number, and solving the resulting equation for x.

Since, by analytic geometry, the slope n of the *normal* PN is the negative reciprocal of the slope of the tangent, we have,

(4) $$n_P = \textit{slope of } PN = -\frac{1}{m_P} = -\frac{1}{[dy/dx]_P},$$

hence the *equation of the normal* is:

$$(5) \qquad (y - y_P) = -\frac{1}{[dy/dx]_P}(x - x_P).$$

29. Tangents and Normals for Curves not in Explicit Form. The equation of the curve may be given in the implicit form

$$(1) \qquad F(x, y) = 0,$$

as in §§ 24–25, pp. 39–41; or the equations in parameter form may be given:

$$(2) \qquad x = f(t),\ y = \phi(t),$$

as in § 20, p. 32. In either of these cases, dy/dx can be found, and this value may be used in the formulas of § 28. No new formulas are necessary.

30. Secondary Quantities. In Fig. 9, § 28, since

$$\tan\alpha\,(= m_P = [dy/dx]_P),\ \text{and}\ AP\,(= y_P),$$

are supposed to be known, the right triangles HAP and PAN can both be solved by trigonometry, and the lengths HA, AN, HP, PN can be found in terms of m_P and y_P:

$$[\text{Subtangent}]_P = HA = AP \div \tan\alpha = y_P \div m_P = [y/m]_P.$$

$$[\text{Subnormal}]_P = AN = AP \cdot \tan\alpha = [y \cdot m]_P, \text{since } \alpha = \angle APN.$$

$$[\text{Length of tangent}]_P = HP = \sqrt{\overline{AP}^2 + \overline{HA}^2}$$
$$= \sqrt{y_P^2 + [y/m]_P^2} = [y\sqrt{1 + (1/m)^2}]_P.$$

$$[\text{Length of normal}]_P = PN = \sqrt{\overline{AP}^2 + \overline{AN}^2}$$
$$= \sqrt{y_P^2 + (y \cdot m)_P^2} = [y\sqrt{1 + m^2}]_P.$$

It is usual to give these lengths the names indicated above; and to calculate the numerical magnitudes without regard to signs, unless the contrary is explicitly stated.

31. Illustrative Examples. In this article, a few typical examples are solved.

EXAMPLE 1. Given the curve $y = x^3 - 12x + 7$ (Ex. 2, p. 21), we have $m = dy/dx = 3x^2 - 12$.

(1) The tangent (T) and the normal (N) at a point where $x = a$ are

$$(T)\ y - (a^3 - 12a + 7) = (3a^2 - 12)(x - a),$$

$$(N)\ y - (a^3 - 12a + 7) = \frac{-1}{3a^2 - 12}(x - a);$$

thus, at $x = 3$, the tangent and normal are

$$(T)\ \ y + 2 = 15(x - 3), \quad (N)\ \ y + 2 = -\tfrac{1}{15}(x - 3).$$

(2) The tangent has a given slope k at points where

$$3x^2 - 12 = k, \text{ i.e. } x = \pm\sqrt{\frac{k + 12}{3}};$$

there are always two points where the slope is the same, if $k > -12$; thus if $k = 0$, $x = \pm 2$; if $k = -9$, $x = \pm 1$; if $k = -12$, $x = 0$; if $k < -12$, no real value for x exists (see Fig. 15, p. 68).

(3) The secondary quantities of § 30 may be calculated without using the formulas of § 30. Thus, at the point where $x = 3$, the tangent (T) cuts the x-axis where $x = 47/15$; the normal (N) cuts the x-axis where $x = -27$. If the student will draw a figure showing these points and lines, he will observe directly that the subtangent is $2/15$, the subnormal 30, the length of the tangent $\sqrt{2^2 + (2/15)^2}$, the length of the normal $\sqrt{30^2 + 2^2}$. These values agree with those given by § 30.

EXAMPLE 2. Given the circle $x^2 + y^2 = 1$, we have $m = dy/dx = -x/y$ [see § 24].

(1) The tangent (T) and normal (N) at a point (x_0, y_0) are

$$(T)\ (y - y_0) = -\frac{x_0}{y_0}(x - x_0), \quad (N)\ (y - y_0) = \frac{y_0}{x_0}(x - x_0);$$

or, since $x_0{}^2 + y_0{}^2 = 1$,

$$(T)\ \ xx_0 + yy_0 = 1, \quad (N)\ \ yx_0 = y_0x;$$

thus, at the point $(3/5, 4/5)$, which lies on the circle, we have

$$(T)\ \ 3x + 4y = 5, \quad (N)\ \ 3y = 4x.$$

(2) The tangent has a given slope k at points where

$$-\frac{x_0}{y_0} = k, \text{ i.e. } x_0 + ky_0 = 0.$$

The coördinates (x_0, y_0) can be found by solving this equation simultaneously with the equation of the circle, or by actually drawing the line $x_0 + ky_0 = 0$. Thus the points where the slope is $+1$ lie on the straight line $x + y = 0$; hence, solving $x + y = 0$ and $x^2 + y^2 = 1$, the coördinates are found to be $x = \pm 1/\sqrt{2}$, $y = \mp 1/\sqrt{2}$; but these points are most readily located in a figure by actually drawing the line $x + y = 0$.

EXERCISES

Find the equation of the tangent and that of the normal, and find the four quantities defined in § 30, for each of the following curves at the point indicated:

1. $y = x^3 - 12x + 7$; $(1, -4)$.
2. $y = \dfrac{2x-1}{3x+2}$; $(-1, 3)$.
3. $9x^2 + y^2 = 25$; $(1, 4)$.
4. $xy + y^2 - 2x = 5$; $(-4, 1)$.
5. $x = y^3 - 3y^2 + 5$; $(3, 1)$.
6. $\begin{cases} x = (1-t)^2 \\ y = (1+t)^2 \end{cases}$; $(1, 1)$.
7. $\begin{cases} x = t^2 + 4t - 1 \\ y = t^3 - 3t + 5 \end{cases}$; $(t = 1)$.
8. The curves of Exs. 1 and 3 pass through the point $(1, -4)$; at what angle do they cross?

Determine the equation of the tangent and that of the normal to each of the following curves at any point (x_0, y_0) on it.

9. $y = kx^2$.
10. $y^2 = 2px$.
11. $x^2 + y^2 = a^2$.
12. $y = kx^3$.
13. $b^2x^2 \pm a^2y^2 = a^2b^2$.
14. $ax^2 + 2bxy + cy^2 = f$.
15. $ax^2 + 2bxy + cy^2 + 2dx + 2ey + f = 0$.
16. $y = (ax + b)/(cx + d)$.

32. Extremes. In § 6, and in numerous examples, we have found points on a curve at which the tangent is horizontal, *i.e.* at which the slope is zero. If the slope of the curve $y = f(x)$ is zero at the point where $x = a$, the curve may go through the point in any one of the ways illustrated in Fig. 10.

In case (a), $f(a)$ is called a maximum of $f(x)$.

In case (b), $f(a)$ is called a minimum of $f(x)$.

The value of $f(x)$ at a point where $x = a$ is a $\begin{Bmatrix} \textit{maximum} \\ \textit{minimum} \end{Bmatrix}$ value if it is $\begin{Bmatrix} \textit{greater than} \\ \textit{less than} \end{Bmatrix}$ any other value of $f(x)$ for values of x *sufficiently near* to $x = a$.

A maximum or a minimum is called an ***extreme value***, or an extreme of $f(x)$.

A value of x for which the slope m is zero is called a ***critical value.*** The corresponding point on the curve is

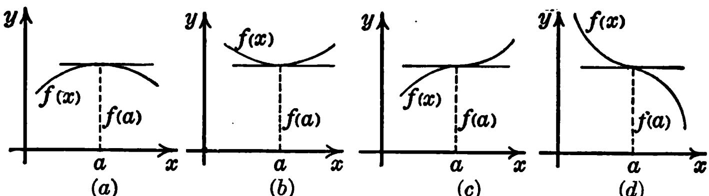

FIG. 10.

called a ***critical point.*** At such a point, $f(x)$ may be a maximum or a minimum, but it is not necessarily either. Thus, in cases (*c*) and (*d*), Fig. 10, the value of $f(a)$ is neither a maximum nor a minimum of $f(x)$.

On the other hand, extremes may also occur at points where the derivative has no meaning, or at points where the function becomes meaningless.

Thus, the curve $y = x^{2/3}$ gives $m = 2/(3\,x^{1/3})$: hence m is meaningless when $x = 0$; in fact, the curve has a vertical tangent at that point. It is easy to see that this is, however, the lowest point on the curve.

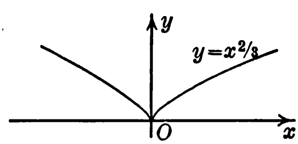

FIG. 11.

Again, if a duplicating apparatus costs \$150, and if the running expenses are 1c. per sheet, the total costs of printing n sheets is $t = 150 + .01\,n$. This equation represents a straight line; geometrically there are no extreme values of t; but practically t is a minimum when $n = 0$, since negative values of n are meaningless. Such cases are usually easy to observe.

33. Fundamental Theorem. We proceed to show that a function $f(x)$ cannot have an extreme except at a critical point; that is, assuming that $f(x)$ and its derivative have definite meanings at $x = a$ and everywhere near $x = a$, *no extreme can occur if the derivative is not zero at* $x = a$.

We are supposing that all our functions are continuous; if, then, the derivative m is positive at $x = a$, it cannot suddenly become negative or zero. Hence m is positive on both sides of $x = a$, and there can be no extreme there.

Likewise if m is negative, the curve is falling near $x = a$ on both sides of $x = a$; there can be no extreme.

34. Final Tests. It is not certain that $f(x)$ has an extreme value at a critical point. To decide the matter, we proceed to determine whether the curve rises or falls to the left and to the right of the critical point: it rises if $m > 0$; it falls if $m < 0$. (See Fig. 10 in § 32.)

Near a *maximum*, the curve rises on the left and falls on the right.

Near a *minimum*, the curve falls on the left and rises on the right.

If the curve rises on both sides, or falls on both sides, of the critical point, there is *no extreme* at that point.

35. Illustrative Examples.

EXAMPLE 1. To find the extreme values of the function $y = f(x) = x^3 - 12x + 7$. (See Ex. 3, p. 8.)

(*A*) *To find the Critical Values.* Set the derivative equal to zero and solve for x:

$$m = \frac{dy}{dx} = 3x^2 - 12;\ 3x^2 - 12 = 0;\ x = 2 \text{ or } x = -2.$$

(*B*) *Precautions.* Notice that $f(x)$ and its derivative each have a meaning for every value of x; hence $x = +2$ and $x = -2$ are the only critical values.

(*C*) *Final Tests.* $m = 3x^2 - 12 = 3(x^2 - 4)$ is positive if x is greater than 2, negative if x is slightly less than 2; hence the curve rises on the right and falls on the left of $x = 2$, therefore $f(2) = -9$ is a minimum of $f(x)$. The student may show that $f(-2) = 23$ is a maximum of $f(x)$. (See Fig. 3, p. 8.)

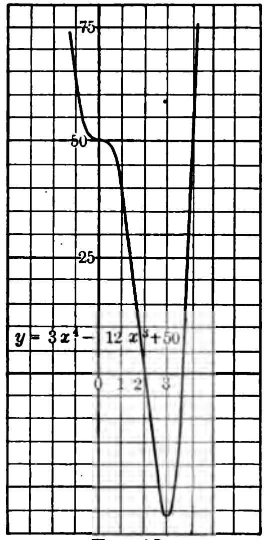

FIG. 12.

EXAMPLE 2. To find the extremes of the function

$$y = f(x) = 3x^4 - 12x^3 + 50.$$

(*A*) *Critical Values.* Setting $dy/dx = 0$, and solving, we find:

$$m = \frac{dy}{dx} = 12x^3 - 36x^2;\ 12x^3 - 36x^2 = 0;$$

$$x = 0, \text{ or } x = 3.$$

(*B*) *Precautions.* y and dy/dx have a meaning everywhere; the only critical values are 0 and 3.

(*C*) *Final Tests.* Near $x = 0$, $m = 12x^2(x - 3)$ is negative on both sides; hence there is no extreme there, though the tangent is horizontal.

Near $x = 3$, $m = 12x^2(x - 3)$ is positive on the right, negative on the left; hence $f(3) = -31$ is a minimum.

The information given above is of great assistance in accurate drawing.

EXAMPLE 3. Two railroad tracks cross at right angles; on one of them an eastbound train going 15 mi. per hour clears the crossing one minute before the engine of a southbound train running at 20 mi. per hour reaches the crossing. Find when the trains were closest together.

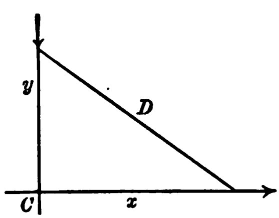

FIG. 13.

Let x and y be the distance in miles of the rear end of the first train and the engine of the second one from the crossing, respectively, at a time t measured in minutes beginning with the instant the first train clears the crossing; then

$$x = \frac{15}{60}t, \quad y = \frac{20}{60}(1 - t), \quad D^2 = x^2 + y^2 = \frac{1}{9} - \frac{2}{9}t + \frac{25}{144}t^2$$

where D is the distance between the trains in miles.

Since D is a positive quantity, it is a minimum whenever D^2 is a minimum; hence we write:

$$m = \frac{d(D^2)}{dt} = -\frac{2}{9} + \frac{25}{72}t; \quad -\frac{2}{9} + \frac{25}{72}t = 0; \quad t = \frac{16}{25};$$

when $t < 16/25$, $m < 0$; if $t > 16/25$, $m > 0$; hence D^2 is diminishing before $t = 16/25$ and increasing afterwards. It follows that D is a minimum when $t = 16/25$. Substituting this value for t, we find the values $x = 4/25$, $y = 3/25$, $D^2 = 1/25$; hence the minimum distance between the trains is 1/5 of a mile, and this occurs 16/25 of a minute after the first train clears the crossing.

EXAMPLE 4. To find the most economical shape for a pan with a square bottom and vertical sides, if it is to hold 4 cu. ft.

Let x be the length of one side of the base, and let h be the height. Let V be the volume and A the total area. Then $V = hx^2 = 4$, whence $h = 4/x^2$; and

$$A = x^2 + 4\,hx = x^2 + \frac{16}{x};$$

whence we find

$$m = \frac{dA}{dx} = 2\,x - \frac{16}{x^2}; \quad 2\,x - \frac{16}{x^2} = 0, \quad x^3 = 8, \quad x = 2.$$

When $x < 2$, $m = 2(x^3 - 8)/x^2$ is negative; when $x > 2$, m is positive; hence A is decreasing when x is increasing toward 2, and A is increasing as x is increasing past 2; therefore $x = 2$ gives the minimum total area $A = 12$. Notice that the height is $h = 4/x^2 = 1$. The correct dimensions are $x = 2$, $h = 1$ (in feet).

EXERCISES

Determine the maximum and minimum values of the following functions and draw the graphs, choosing suitable scales.

1. $y = x^3 - 6\,x^2 + 2.$

2. $s = 2\,t^3 - 6\,t^2 - 18\,t + 15.$

3. $p = q^3 - 6\,q^2 - 15\,q.$

4. $y = x^3 + 2\,ax^2 + a^2x.$

5. $x = y^4 - 4\,y^2 + 2.$

6. $v = u^4 - 4\,u^3 + 4\,u^2 + 3.$

7. $m = n^5 - 5\,n^4 + 5\,n^3 + 1.$

8. $A = r^6 - 6r^4 + 4r^3 + 9r^2 - 12r + 4.$

9. $s = (2\,t - 1)\,(1 - t)^2.$

10. $V = h(h - 1)^2.$

11. $r = (s^2 - 1)\,(s^2 - 4).$

12. $x = (y - 2)^3\,(y + 3)^3.$

13. $y = \dfrac{(x + 2)^2}{(x + 1)^2}.$

14. $v = u + \dfrac{a^2}{u}.$

15. $y = \dfrac{x-2}{x^2 - 2x + 4}.$ **16.** $K = \dfrac{h}{ah^2 + bh + c}.$

17. $y = \dfrac{x^3 - x}{x^4 - x^2 + 1}.$ **18.** $Q = k + \sqrt{1-k}.$

19. $D = r\sqrt{8 - r^2}.$ **20.** $R = \sqrt[3]{x+6} - x.$

21. What is the largest rectangular area that can be inclosed by a line 80 feet long?

22. What must be the ratio of the sides of a right triangle to make its area a maximum, if the hypothenuse is constant?

23. Determine two possible numbers whose product is a maximum if the sum of their squares is 98. Is there any minimum?

24. Determine two numbers whose product is 100 and such that the sum of their squares is a minimum. Is there any maximum? Did you account for negative possible values of the two numbers?

25. What are the most economical proportions for a cylindrical can? Is there any most extravagant type? Mention other considerations which affect the actual design of a tomato can. Is an ordinary flour barrel this shape? What considerations enter in making a barrel?

26. What are the most economical proportions for a cylindrical pint cup? (1 pint = $28\frac{7}{8}$ cu. in.) Mention considerations of design.

27. Determine the best proportions for a square tank with vertical sides, without a top. Is there any most extravagant shape?

28. The strength of a rectangular beam varies as the product of the breadth by the square of the depth. What is the form of the strongest beam that can be cut from a given circular log? Mention some other practical considerations which affect actual sawing of timber.

29. The stiffness of a rectangular beam varies as the product of the breadth by the cube of the depth. What are the dimensions of the stiffest beam that can be cut from a circular log?

30. Is a beam of the commercial size $3'' \times 8''$ stronger (or stiffer) than the size $2'' \times 12''$ (1) when on edge, (2) when lying flat?

[Commercial sizes of lumber are always a little short.]

31. What line through the point (3, 4) will form the smallest triangle with the coördinate axes? Is there any other minimum? maximum?

32. Determine the shortest distance from the point (0, 3) to a point on the hyperbola $x^2 - y^2 = 16$. Show that it lies on the normal.

[HINT. Use the square of the distance.]

33. The distance D from the point (2, 0) to any point of the circle $x^2 + y^2 = 1$ is given by the equation $D^2 = 5 - 4x$. Discover the maximum and minimum values of D^2, and show why the rule fails.

34. Show that the maximum and minimum on the cubic $y = x^3 - ax + b$ are at equal distances from the y-axis. Compute y at these points.

35. Show that the cubic $x^3 - ax + b = 0$ has three real roots if the extreme values of the left-hand side (Ex. 34) have different signs. Express this condition algebraically by an inequality which states that the *product* of the two extreme values is negative.

[Any cubic can be reduced to this form by the substitution $x = x' + k$; hence this test may be applied to any cubic.]

36. Show that if the equation $x^3 - ax + b = 0$ has two real roots, the derivative of the left-hand side (*i.e.* $3x^2 - a$) must vanish somewhere between the two roots. Show that the converse is not true.

37. The line $y = mx$ passes through the origin for any value of m. The points (1, 2.4), (3, 7.6), (10, 25) do *not* lie on any one such line: the values of y found from the equation $y = mx$ at $x = 1, 3, 10$ are m, $3m$, $10m$; the differences between these and the given values of y are $(m - 2.4)$, $(3m - 7.6)$, $(10m - 25)$. It is usual to assume that that line for which *the sum of the squares of these differences*

$$S = (m - 2.4)^2 + (3m - 7.6)^2 + (10m - 25)^2$$

is least is the best compromise. Show that this would give $m = 2.50$ (nearly). Draw the figure.

38. In an experiment on an iron rod the amount of stretching s (in thousandths of an inch) and the pull p (in hundreds of pounds) were found to be $(p = 5,\ s = 4)$, $(p = 10,\ s = 8)$, $(p = 20,\ s = 17)$. Find the best compromise value for m in the equation $s = m \cdot p$, under the assumption of Ex. 37. *Ans.* About 5/6.

39. A city's bids for laying cement sidewalks of uniform width and specifications are as follows: Job No. 1: length = 250 ft., cost, $110; Job No. 2: length, 600 ft., cost, $250; Job No. 3: 1500 ft., cost, $630. Find the price per foot for such walks, under the assumption of Ex. 37. How much does this differ from the arithmetic average of the price per foot in the three separate jobs?

40. The amount of water in a standpipe reaches 2000 gal. in 250 sec., 5000 gal. in 610 sec. From this information (which may be slightly faulty) find the rate at which water was flowing into the tank, under assumption of Ex. 37.

41. The values 1 in. = 2.5 cm., 1 ft. = 30.5 cm. are frequently quoted, but they do not agree precisely. The number of centimeters c, and the number of inches i, in a given length are surely connected by an equation of the form $c = ki$. Show that the assumptions of Ex. 37 give $k = 2.541$. Is this the same as the average of the values in the two cases? Which result is more accurate?

42. In experiments on the velocity of sound, it was found that sound travels 1 mi. in 5 sec., 3 mi. in 14.5 sec. These measurements do not agree precisely. Show that the compromise of Ex. 37 gives the velocity of sound 1088 ft. per second. How does this compare with the *average* of the two velocities found in the separate experiments?

43. A quantity of water which at 0° C. occupies a volume v_0, at θ° C. occupies a volume

$$v = v_0 (1 - 10^{-4} \times .5758\,\theta + 10^{-5} \times .756\,\theta^2 - 10^{-7} \times .351\,\theta^3).$$

Show that the volume is least (density greatest), at 4° C. (nearly).

44. Determine the rectangle of greatest perimeter that can be inscribed in a given circle. Is there any minimum?

45. What is the largest rectangle that can be inscribed in an isosceles triangle? Is there any minimum?

46. Find the area of the largest rectangle that can be inscribed in a segment of the parabola $y^2 = 4\,ax$ cut off by the line $x = h$.

47. Determine the cylinder of greatest volume that can be inscribed in a given sphere. Is there also a minimum?

48. Determine the cylinder of greatest convex surface that can be inscribed in a sphere. Is there a minimum?

49. Determine the cylinder of greatest total surface (including the area of the bases) that can be inscribed in a given sphere.

50. What is the volume of the largest cone that can be inscribed in a given sphere?

51. What is the area of the maximum rectangle that can be inscribed in the ellipse $x^2/a^2 + y^2/b^2 = 1$?

CHAPTER VI

SUCCESSIVE DERIVATIVES

36. Time-rates. In all the applications, derivatives are *rates of increase* (or decrease) of some quantity with respect to some other quantity which is taken as the standard of comparison, or independent variable.

Among all rates, those which occur most frequently are ***time-rates***, that is, rate of change of a quantity with respect to the time.

37. Speed. Thus the speed of a moving body is the time-rate of increase of the distance it has traveled:

$$(1) \qquad v = speed^{*} = \lim_{\Delta t \to 0} \frac{\Delta s}{\Delta t} = \frac{ds}{dt},$$

as in § 7, p. 9, and in numerous examples.

38. Tangential Acceleration. The *speed* itself may change; *the time-rate of change of speed is called the* ***acceleration along the path****, or the* ***tangential acceleration***†.

$$(2) \qquad j_T = tangential\ acceleration\ \dagger = \lim_{\Delta t \to 0} \frac{\Delta v}{\Delta t} = \frac{dv}{dt}.$$

* The *speed* v is distinguished from the velocity $\mathbf{v}$ by the fact that the speed does not depend on the direction; when we speak of velocity we shall always denote it by $\mathbf{v}$ (in black-faced type) and we shall specify the direction.

† The ***general acceleration*** $\mathbf{j}$ is also a directed quantity; when we speak of the ***acceleration*** $\mathbf{j}$ (not tangential acceleration j_T) we shall denote it by $\mathbf{j}$, and give its direction. As in the case of speed, the letter j, in italic type, denotes the value of $\mathbf{j}$ without its direction.

Thus for a body falling from rest, if g represents the gravitational constant,

$$s = \tfrac{1}{2} gt^2;$$

hence

$$v = \frac{ds}{dt} = gt,$$

and

$$j_T = \frac{dv}{dt} = g;$$

it follows that the tangential acceleration of a body falling from rest is constant; that constant is precisely the gravitational constant g.*

In obtaining the tangential acceleration, we actually differentiate the distance s twice, once to get v, and again to get dv/dt or j_T, hence the tangential acceleration is also said to be the ***second derivative*** of the distance s passed over.

39. Second Derivatives, Flexion. It often happens, as in § 38, that we wish to differentiate a function twice. In any case, given $y = f(x)$, the slope of the graph is

$$m = \frac{dy}{dx} = \lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x}.$$

The slope itself may change (and it always does except on a straight line); *the rate of change of the slope with respect to x will be called the flexion* † *of the curve:*

$$b = \textit{flexion} = \frac{dm}{dx} = \lim_{\Delta x \to 0} \frac{\Delta m}{\Delta x},$$

and will be denoted by b, the initial letter of the word *bend*.

Thus for $y = x^2$, we find $m = 2x$, $b = 2$; ‡

* The value of g is approximately 32.2 ft. per second per second = 981 cm. per second per second.

† The word *curvature* is used in a somewhat different sense. See § 86, p. 139.

‡ The flexion for this parabola is constant; note that this means the rate of change of m per unit increase in x, not per unit increase in length along the curve.

for $\quad y = x^3, \quad m = 3x^2, \quad b = 6x;$

for $\quad y = x^3 - 12x + 7, \quad m = 3x^2 - 12, \quad b = 6x;$

for *any* straight line $y = kx + c$, $m = k$, $b = 0$.

The value of b is obtained by differentiating the given function twice; the result is called a ***second derivative***, and is represented by the symbol:

$$\frac{d^2y}{dx^2} = \frac{d}{dx}\left(\frac{dy}{dx}\right) = \frac{dm}{dx} = b.$$

Likewise, the tangential acceleration in a motion is

$$\frac{d^2s}{dt^2} = \frac{d}{dt}\left(\frac{ds}{dt}\right) = \frac{dv}{dt} = j_T.$$

If the relation between s and t is represented graphically, the *speed* is represented by the *slope*, the *tangential acceleration* by the *flexion*, of the graph. Thus if $s = gt^2/2$ be represented graphically, as in Fig. 4, p. 10, the *slope* of the (t, s) curve is

$$m = slope = \frac{ds}{dt} = gt = speed = v,$$

and the flexion of the (t, s) curve is

$$b = flexion = \frac{dm}{dt} = \frac{d^2s}{dt^2} = \frac{dv}{dt} = g = tangential\ acceleration = j_T.$$

40. Speed and Acceleration. Parameter Forms. Let the equations

$$x = f(t), \quad y = \phi(t)$$

represent the position of a moving point P in terms of time t as variable. Then, as in § 8,

(1) $\displaystyle v_x = \frac{dx}{dt}$ = horizontal component of the speed of P;

(2) $\displaystyle v_y = \frac{dy}{dt}$ = vertical component of the speed of P;

(3) $v = \sqrt{v_x^2 + v_y^2}$ = total speed of P,
in the direction $\tan^{-1}(v_y/v_x)$.

Further,

(4) $j_x = \dfrac{d^2x}{dt^2}$ = horizontal acceleration of P;

(5) $j_y = \dfrac{d^2y}{dt^2}$ = vertical acceleration of P;

(6) $j = \sqrt{j_x^2 + j_y^2}$ = total acceleration of P,
in the direction $\tan^{-1}(j_y/j_x)$.

Note that the direction of v is along the tangent to the path of P, since $v_y/{}_xv$ is equal to dy/dx, or m. But the total acceleration j is not, in general, in the direction of the path of P, since j_y/j_x is ordinarily quite different from v_y/v_x. Hence j and j_T are usually different.* To get j_T, calculate dv/dt from (3).

EXAMPLE. Let the parametric equations of the path be

$$x = t^2, \quad y = 1/t^2 (= t^{-2}).$$

To plot the path take a series of values of t:

$$t = 0,\ \tfrac{1}{2},\ 1,\ 3/2,\ 2,\ \ldots;$$
$$x = 0,\ \tfrac{1}{4},\ 1,\ 9/4,\ 4,\ \ldots;$$
$$y = \infty,\ 4,\ 1,\ 4/9,\ \tfrac{1}{4},\ \ldots.$$

$$v_x = 2t, \qquad j_x = 2,$$
$$v_y = -2t^{-3}, \qquad j_y = 6t^{-4},$$
$$v = 2\sqrt{t^2 + t^{-6}}. \qquad j = 2\sqrt{1 + 9t^{-8}}.$$
$$j_T = \frac{dv}{dt} = \frac{2t - 6t^{-7}}{\sqrt{t^2 + t^{-6}}}. \qquad ([\mathrm{IV}], \S\, 22.)$$

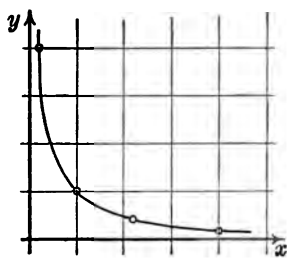

FIG. 14.

* The reason for this difference is not difficult: j_T is the acceleration *in the path itself;* j is the *total* acceleration, part of its effect being precisely to *make the path curved;* hence a part of j is expended not to *increase the speed,* but to change the *direction* of the speed, *i.e.* to *bend the path.* Notice that Ex. 33, p. 65, represents a straight line path; on it $j_T = j$; this holds *only* on straight line paths. In uniform motion on a circle, for example, $j_T = 0$.

EXERCISES

[In addition to this list, the second derivatives of some of the functions in the preceding exercises may be calculated.]

Calculate the first and second derivatives in the following exercises. Interpret these exercises geometrically, and also as problems in motion, with s and t in place of y and x.

1. $y = x^2 + 5x - 4.$	**11.** $y = \sqrt{x} + \sqrt{x^2 + 1}.$
2. $y = -x^2 + 4x - 4.$	**12.** $y = (2 - 3x)^2 (3 + x).$
3. $y = 2x^2 - x - 15.$	**13.** $y = (x + 2)^3 (x^2 - 1).$
4. $y = -5x^2 - x - 15.$	**14.** $y = \sqrt{1 + x} \div \sqrt{1 - x}.$
5. $y = x^2 - \frac{5}{2}x - 21.$	**15.** $y = ax + b.$
6. $y = -x^3 + 3x^2 + 1.$	**16.** $y = c$ (a constant).
7. $y = 2x^3 + 3x^2 - 36x - 20.$	**17.** $y = ax^2 + bx + c.$
8. $y = -x^4 + 8x^2 + 2.$	**18.** $y = c(x - a)^n.$
9. $y = x^4 - 2x^3 + 5x^2 + 2.$	**19.** $y = (x - a)^m (x - b)^n.$
10. $y = (1 + x) \div (1 - x).$	**20.** $y = Ax^{-k}.$

21. Show that the flexion of a straight line is everywhere zero.

22. Show that if the distance passed over by a body is proportional to the time the tangential acceleration is zero. What is the speed?

23. Show that the flexion of the curve $y = ax^2 + bx + c$ is everywhere the same, and equal to twice the coefficient of x^2.

24. Show that if the space-time equation is $s = at^2 + bt + c$, the acceleration is always the same and equal to twice the coefficient of t^2. Is such a motion at all liable to occur in nature?

25. Find the flexion of the curve $y = 1/x$. Show that it resembles y itself in some ways. Does the slope also resemble y?

26. Can you interpret Ex. 25 as a motion problem? What is true at the *beginning* of the motion ($t = 0$)? Can a curve with a vertical asymptote represent a motion? Can a *piece* of such a curve?

27. Find the flexion of the curve $y = (x - 2)^3 (x + 3)^2 (x - 4)$. Show that the flexion has a factor $(x - 2)$, while the slope has a factor $(x - 2)^2 (x + 3)$.

28. Show that the flexion of the curve $y = (x+a)^3 (x^2+3)$ has a factor $(x+a)$.

29. If the function $y = f(x)$, where $f(x)$ is a polynomial, has a factor $(x-\alpha)^3$, show that dy/dx has a factor $(x-\alpha)^2$, and d^2y/dx^2 has a factor $(x-\alpha)$.

30. If the equation $x^5 + ax^4 + bx^3 + cx^2 + dx + e = 0$ has a triple root $x = \alpha$, show that the equation $20x^3 + 12ax^2 + 6bx + 2c = 0$ has a factor $x - \alpha$.

31. Show how to find the double and triple roots of any algebraic equation by the Highest Common Divisor process.

32. If the equations of the curve in parameter form are $x = t^3$, $y = t^2$, find the slope m and the flexion b in terms of t.

$$\left[\text{Hint.}\quad m = \frac{dy}{dx} = \frac{dy}{dt} \div \frac{dx}{dt},\quad b = \frac{dm}{dx} = \frac{dm}{dt} \div \frac{dx}{dt}.\right]$$

For each of the following curves, proceed as in Ex. 32. Calculate also the values, in terms of t, of each of the six quantities mentioned in § 40, and the value of j_T. Compare j and j_T.

33. $x = a + bt,\ y = c + dt.$ **34.** $x = t^2,\ y = t^3.$

35. $x = t,\ y = t^{-2};\ t = 1$ and 2. **36.** $x = 1 + t,\ y = \dfrac{1}{1-t};\ t = \pm 2.$

37. $x = \dfrac{t}{1+t},\ y = \dfrac{1-t}{t};\ t = 1.$ **38.** $x = \dfrac{3t}{1+t^3},\ y = \dfrac{3t^2}{1+t^3};\ t = 1.$

41. Concavity. Points of Inflexion. If the flexion $b = dm/dx$ is positive, the slope is increasing, and the curve turns upwards, or is *concave upwards;* if the flexion is negative, the slope is decreasing, and the curve is *concave downwards.*

Thus $y = x^2$ is concave upwards everywhere, since $b = 2$ is positive. For $y = x^3$ we find $b = 6x$, which is positive when x is positive, and negative when x is negative; hence $y = x^3$ is concave upwards at the right, and concave downwards at the left of the origin.

A point at which the curve changes from being concave upwards to being concave downwards, or conversely, is called a *point of inflexion.*

The value of the flexion b changes from positive to negative,

or conversely, in passing such a point; hence, *the value of b at a point of inflexion is zero*, if it has any value there.*

Thus the origin is a point of inflexion on the curve $y = x^3$, for the curve is concave downwards on the left, concave upwards on the right, of the origin.

42. Second Test for Extremes. In seeking the extreme values of a function $y = f(x)$, we find first the *critical points*, *i.e.* the points at which the tangent is horizontal.

If, at a critical point, $b = d^2y/dx^2 > 0$, the curve is also *concave upwards*,† and the function has a *minimum* there; if $b < 0$, the curve is *concave downwards*, and $f(x)$ has a *maximum;* that is,

$$\textit{if } m = \frac{dy}{dx} = 0 \textit{ and } b = \frac{d^2y}{dx^2}\begin{Bmatrix} > 0 \\ < 0 \end{Bmatrix} \textit{at } x = a, f(a) \textit{ is a} \begin{Bmatrix} \textit{minimum} \\ \textit{maximum} \end{Bmatrix}.$$

Whenever the flexion is not zero at a critical point, this method usually furnishes an easy final test for extremes. If the flexion is zero, no conclusion can be drawn directly by this method.‡ (See, however, § 34.)

43. Illustrative Examples.

EXAMPLE 1. Consider the function $y = x^3 - 12x + 7$. See Ex. 3, p. 8, and Ex. 1, p. 54. The slope and the flexion are, respectively,

$$m = \frac{dy}{dx} = 3x^2 - 12, \quad b = \frac{d^2y}{dx^2} = \frac{dm}{dx} = 6x.$$

* Points where the tangent is vertical, for example, may be points of inflexion.

† The curve is then also concave upwards on both sides of the point; if the curve is concave upwards on one side and downwards on the other, b must be zero if it exists at the point.

‡ Even in this case one *may* decide by determining whether the curve is concave upwards or downwards on both sides of the point; but the method of § 34 is usually superior.

The critical points are $x = \pm 2$. Since $6x$ is positive when x is positive, b is positive for $x > 0$; likewise $b < 0$ when $x < 0$. Hence the curve is concave upwards when $x > 0$, and concave downwards when $x < 0$. At $x = +2$, $b > 0$, hence by § 42, y has a minimum at $x = +2$; at $x = -2$, $b < 0$, hence y has a maximum (compare p. 8 and p. 54).

To find a point of inflexion first set $b = 0$;

$$b = \frac{dm}{dx} = \frac{d^2y}{dx^2} = 6x = 0, \text{ i.e. } x = 0.$$

Since dm/dx is negative for $x < 0$ and positive for $x > 0$, the given curve is concave downwards on the left and concave upwards on the right of this point; hence $x = 0$, $y = 7$ is a point of inflexion. (See Fig. 15, and § 44, p. 68.)

Example 2. Consider the function $y = 3x^4 - 12x^3 + 50$ (Ex. 2, p. 55).

The slope and the flexion are, respectively,

$$m = \frac{dy}{dx} = 12x^3 - 36x^2; \quad b = \frac{dm}{dx} = \frac{d^2y}{dx^2} = 36x^2 - 72x.$$

The critical points are $x = 0$, $x = 3$. At $x = 3$, $b = 108 > 0$, hence y is a minimum there. At $x = 0$, $b = 0$, and no conclusion is reached by this method (compare, however, p. 55). To find points of inflexion, first set $b = 0$;

$$b = \frac{dm}{dx} = \frac{d^2y}{dx^2} = 36x^2 - 72x = 0, \text{ i.e. } x = 0 \text{ or } x = 2.$$

Near $x = 0$, at the left, $dm/dx = 36x(x-2)$ is positive; at the right, negative; the given curve is concave upwards on the left, downwards on the right, and $(x = 2,\ y = 2)$ is a point of inflexion. (See Fig. 13.)

Example 3. For a body thrown vertically upwards, the distance s from the earth is:

$$s = -\tfrac{1}{2}gt^2 + v_0t,$$

where v_0 is the speed with which it is thrown.

The speed and the tangential acceleration are, respectively,

$$v = \frac{ds}{dt} = -gt + v_0; \quad j_T = \frac{d^2s}{dt^2} = \frac{dv}{dt} = -g.$$

If we draw a graph of the values of s and t, the speed v (slope of the graph) is zero when

$$v = -gt + v_0 = 0, \quad \text{i.e. } t = v_0/g,$$

that is, the point is a critical point on the graph. The tangential acceleration (flexion of the graph) is negative everywhere, hence the graph is *concave downwards.*

In particular, at the critical point just found, b is negative; hence s has a maximum there:

$$s = -\frac{1}{2}gt^2 + v_0t = \frac{1}{2}\frac{v_0^2}{2g}, \text{ when } t = \frac{v_0}{g}.$$

Fig. 17 is drawn for the special values $v_0 = 64$ and $g = 32$.

44. Derived Curves. It is very instructive to draw in the same figure graphs which give the values of the original function, its derivative, and its second derivative.

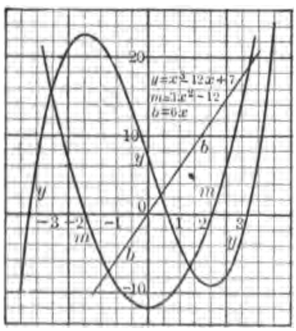

FIG. 15.

These graphs of the derivatives are called the ***derived curves;*** they represent the *slope* (or *speed* in case of a motion) and the *flexion* (or *tangential acceleration*).

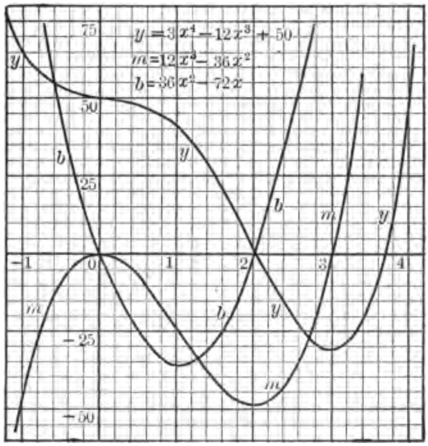
The figures for the curves of Exs. 1 and 2 of § 43 are appended. The student should show that each statement made in § 43 and each statement made on p. 67, for each of the examples, is illustrated and verified in these figures.

The similar curves for space, speed, and acceleration are drawn in Fig. 17, for the motion of a body thrown upwards:

$$s = -\tfrac{1}{2}gt^2 + v_0t \text{ for } g = 32,\ v_0 = 64.$$

Verify the statements made in Ex. 3, § 43.

In drawing such curves, the second derivative should be drawn first of all; the information it gives should be used in drawing the graph of the first derivative, which in turn should be used in drawing the graph of the original function.



$y = 3x^4 - 12x^3 + 50$
$m = 12x^3 - 36x^2$
$b = 36x^2 - 72x$

EXERCISES

1. Draw, in the order just indicated, the first and second derived curves in Ex. 1, p. 56, and show that each step of your work in that example is exhibited by these figures.

2. Draw the derived curves for Exs. 2, 4, 6, 14, p. 56; and show their connection with your previous work.

3. Draw the original and the derived curves for the function $y = x^3 - 6x^2 - 15x - 6$. Find the extreme values of y, and explain the figures. For what value of x is the flexion zero? Does this give a point of inflexion on the original curve?

Find the extreme values of y and the points of inflexion on the following curves; in each case draw complete figures:

4. $y = 2x^3 - 3x^2 - 72x$.

5. $y = 4x^3 + 6x^2 - 24x$.

6. $y = x^3 + x^2$.

7. $y = x^4 - 6x^2 - 40$.

8. $y = x(x+2)^3$.

9. $y = Ax^2 + Bx + C$.

10. $y = mx + n$.

11. $y = \sqrt{x}$.

12. $y = x^3 - px + q$.

13. $y = x^2 - 16/x$.

14. Show that the flexion of the hyperbola $xy = a^2$ varies inversely as the cube of the abscissa x.

15. Show that the flexion of the conic $Ax^2 + By^2 = 1$ (ellipse or hyperbola) varies inversely as the cube of the ordinate y.

16. What is the effect upon the flexion of changing the sign of a in the equation $y = ax^2 + bx + c$?

17. A beam of uniform depth is said to be of "uniform strength" (in resisting a given load) if the actual shape of its upper surface under the load is of the form $y = ax^2 + bx + c$, where x and y represent horizontal and vertical distances measured from the middle point of the beam's surface in its original (unbent) position. Show that the flexion of such a beam is constant.

18. Show that the addition of a constant to the value of y does not affect the slope or the flexion.

19. Show that the addition of a term of the form $kx + c$ to the value of y does not affect the flexion. What effect does it have upon the slope?

20. Show, by means of Exs. 18 and 19, that any beam in which the flexion is constant has the form specified in Ex. 17.

21. Show, by a process precisely similar to that of Ex. 20 that a motion in which the tangential acceleration is constant is defined by an equation of the form $s = at^2 + bt + c$.

22. Find, by the methods of Exs. 18–21, what the form of y must be if the slope is:

$$(a)\ \frac{dy}{dx} = 0;\quad (b)\ \frac{dy}{dx} = -3;\quad (c)\ \frac{dy}{dx} = 6x;\quad (d)\ \frac{dy}{dx} = ax + b.$$

23. What is the form of y if the flexion is 6? if the flexion is $2x + 3$? if the flexion is zero?

24. If a beam of length l is supported only at both ends, and loaded by a weight at its middle point, its deflection y at a distance x from one end is $y = k\ (3\,l^2x - 4\,x^3)$, provided the cross-section of the beam is constant. Find the flexion and show that there are no points of inflexion between the supports.

25. If the beam of Ex. 24 is rigidly fixed at both ends, and loaded at its middle point, the deflection of each half of the beam is $y = k\ (3\,lx^2 - 4\,x^3)$, where x is measured from either end. Show that there is a point of inflexion at a distance $l/4$ from the end, and that the greatest deflection is at the middle point.

Find the points of inflexion and the point of maximum deflection of a uniform beam of length l whose deflection is:

26. $y = k\ (3\,lx^2 - x^3)$.

[Beam rigidly embedded at one end, loaded at other end. Origin at fixed end.]

27. $y = k\ (3\,x^2l^2 - 2\,x^4)$.

[Beam freely supported at both ends, loaded uniformly. Origin at lowest point.]

28. $y = k\ (6\,l^2x^2 - 4\,lx^3 + x^4)$.

[Beam embedded at one end only; loaded uniformly. Origin at fixed end.]

29. $y = k\ (l^3x - 3\,lx^3 + 2\,x^4)$.

[Beam embedded at one end, supported at the other end; loaded uniformly. Origin at free end.]

45. Angular Speed. If a wheel turns, the angle θ which a given spoke makes with its original position changes with the time, *i.e.* θ is a function of the time:

$$\theta = f(t).$$

The time-rate of change of the angle θ is called the ***angular speed****; it is denoted by ω:*

$$\omega = \textit{angular speed} = \frac{d\theta}{dt} = \lim_{\Delta t \to 0} \frac{\Delta\theta}{\Delta t}.$$

46. Angular Acceleration. The angular speed may change; *the time-rate of change of the angular speed is called the* ***angular acceleration****; it is denoted by α:*

$$\alpha = \textit{angular acceleration} = \lim_{\Delta t \to 0} \frac{\Delta\omega}{\Delta t} = \frac{d\omega}{dt} = \frac{d^2\theta}{dt^2}.$$

EXAMPLE 1. A flywheel of an engine starts from rest, and moves for 30 seconds according to the law

$$\theta = -\frac{1}{1800}t^4 + \frac{1}{30}t^3,$$

where θ is measured in degrees, after which it rotates uniformly.

Then

$$\omega = \frac{d\theta}{dt} = -\frac{1}{450}t^3 + \frac{1}{10}t^2,$$

and

$$\alpha = \frac{d\omega}{dt} = -\frac{1}{150}t^2 + \frac{2}{10}t.$$

This example furnishes an instance in which *the derived curves, i.e.* the graphs which show the values of ω and of α *are more important than the original curve;* for the total angle described is relatively unimportant.

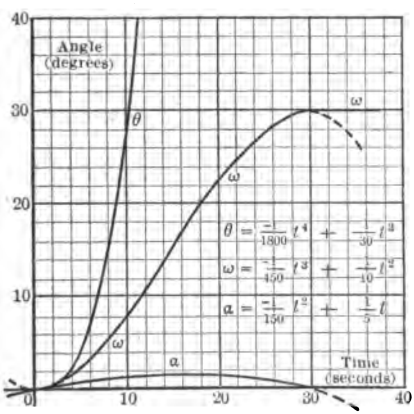

FIG. 18.

In the figure a scale is chosen which shows particularly well the

variation of ω; θ is allowed to run off of the figure completely, since its values are uninteresting.

The acceleration α is so arranged that it does not suddenly drop to zero when the flywheel is allowed to run uniformly; and the values of α are never large. Something resembling this figure is what actually occurs in starting a large flywheel.

In actual practice with various machines, curves of this type are often drawn *experimentally*. The equations serve only as approximations to the reality, but they are often indispensable in calculating other related quantities, such as the acceleration in this example.

Curves which resemble the graph of ω in this example occur frequently. (See §§ 87, 134.)

EXERCISES

1. A flywheel rotates so that $\theta = t^3 \div 1000$, where θ is the angle of rotation (in degrees) and t is the time (in seconds). Calculate the angular speed and acceleration, and draw a figure to represent each of them.

2. Suppose that a wheel rotates so that $\theta = t^3 \div 1000$ where θ is measured in *radians* [1 radian $= 180°/\pi$]. Is its speed greater than or less than that of the wheel in Ex. 1? What is the ratio of the speeds in the two cases?

3. If a wheel moves so that $\theta = -t^4/16 - t/32$, where θ is measured in radians and t in minutes, find the angular speed and acceleration in terms of radians and minutes; in terms of revolutions and minutes; in terms of radians and seconds (of time).

4. If a Ferris wheel turns so that $\theta = 20\,t^2$ while changing from rest to full speed, where θ is in degrees and t in minutes, when will the speed reach 20 revolutions per hour?

5. If the angular speed is $\omega = kt$, as in Ex. 4, show that the acceleration α is constant. Conversely, show that if $\alpha = k$, and if t is the time since starting, $\omega = kt$.

6. Express the linear speed of a point on the rim of a wheel 10 ft. in diameter when the angular speed is 4 R. P. M.

7. Find the linear speed and the tangential acceleration of a point on the rim of the wheel of Ex. 1, § 46, if the wheel is 5 ft. in diameter. What are they when $t = 30$ sec.?

47. Related Rates. If a relation between two quantities is known, the time-rate of change of one of them can be expressed in terms of the time-rate of change of the other.

Thus, in a spreading circular wave caused by throwing a stone into a still pond, the circumference of the wave is

$$c = 2\,\pi r, \tag{1}$$

where r is the radius of the circle. Hence

$$\frac{dc}{dt} = 2\,\pi\frac{dr}{dt}; \tag{2}$$

or, the time-rate at which the circumference is increasing is $2\,\pi$ times the time-rate at which the radius is increasing. Dividing both sides by dr/dt, we find

$$\frac{dc}{dt} \div \frac{dr}{dt} = 2\,\pi = \frac{dc}{dr} = dc \div dr;$$

that is, *the ratio of the time-rates is the derivative of c with respect to r;* or, *the ratio of the time-rates is equal to the ratio of the differentials.*

The fact just mentioned is true in general; if y and x are any two related variables which change with the time, it is true (Rule [VIIa], p. 32) that:

$$\frac{dy}{dt} \div \frac{dx}{dt} = \frac{dy}{dx} = dy \div dx,$$

that is, *the ratio of the time-rates of y and x is equal to the ratio of their differentials, i.e.* to the *derivative dy/dx.*

EXAMPLE 1. Water is flowing into a cylindrical tank. Compare the rates of increase of the total volume and the increase in height of the water in the tank, if the radius of the base of the tank is 10 ft. Hence find the rate of inflow which causes a rise of 2 in. per second; and find the increase in height due to an inflow of 10 cu. ft. per second. Consider the same problem for a conical tank.

(*A*) The volume V is given in terms of the height h by the formula:

$$V = \pi r^2 h = 100\,\pi h,$$

hence

$$\frac{dV}{dt} = 100\,\pi\,\frac{dh}{dt};$$

or, the rate of increase in volume (in cubic feet per second) is 100 π times the rate of increase in height (in feet per second).

If $dh/dt = 1/6$ (measured in feet per second), $dV/dt = 100\,\pi/6 =$ (roughly) 52.3 (cubic feet per second). If $dV/dt = 10$, $dh/dt = 10 \div 100\,\pi =$ (roughly) .031 (in feet per second) $=$ 22.3 (in inches per minute).

(*B*) If the reservoir is *conical*, we have

$$V = \tfrac{1}{3}\,\pi r^2 h = \tfrac{1}{3}\,\pi h^3 \tan^2 \alpha,$$

where r is the radius of the water surface, h is the height of the water, and α is the half-angle of the cone; for $r = h \tan \alpha$. In this case

$$\frac{dV}{dt} = \pi h^2 \tan^2 \alpha\,\frac{dh}{dt},$$

which varies with h. If $\alpha = 45°$ ($\tan \alpha = 1$), at a height of 10 ft., a rise 1/6 (feet per second) would mean an inflow of $\pi h^2 \times (1/6) = 100\,\pi/6 = 52.3$ (cubic feet per second). At a height of 15 feet, a rise of 1/6 (feet per second) would mean an inflow of $225\,\pi/6 =$ (roughly) 117.8 (cubic feet per second). An inflow of 100 (cubic feet per second) means a rise in height of $100/\pi h^2$, which varies with the height; at a height of 5 ft., the rate of rise is $4/\pi = 1.28$ (feet/second).

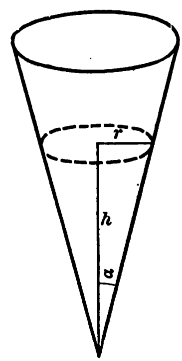

FIG. 19.

EXAMPLE 2. A body thrown upward at an angle of 45°, with an initial speed of 100 ft. per second, neglecting the air resistance, etc., travels in the parabolic path

$$y = -\frac{gx^2}{10000} + x,$$

where x and y mean the horizontal and vertical distances from the starting point, respectively; g is the gravitational constant $= 32.2$ (about); and the horizontal speed has the constant value $100/\sqrt{2}$. Find the vertical speed at any time t, and find a point where it is zero.

The horizontal speed and the vertical speed, *i.e.* the time-rate of change of x and y, respectively, are connected by the relation (see §§ 8, 20).

$$\frac{dy}{dt} \div \frac{dx}{dt} = \frac{dy}{dx} = -\frac{gx}{5000} + 1;$$

hence
$$\frac{dy}{dt} = \left(-\frac{gx}{5000} + 1\right)\frac{dx}{dt} = -\frac{gx}{50\sqrt{2}} + \frac{100}{\sqrt{2}}.$$

This vertical speed is zero where

$$-\frac{gx}{50\sqrt{2}} + \frac{100}{\sqrt{2}} = 0, \textit{i.e. } x = \frac{5000}{g} = 155.3 \text{ (about)},$$

which corresponds to $y = 2500/g = 77.7$ (about). At this point the vertical speed is zero; just before this it is positive, just afterwards it is negative. When $x = 0$ the value of dy/dt is $100/\sqrt{2}$; when $x = 2500/g$, $dy/dt = 50/\sqrt{2}$; when $x = 7500/g$, $dy/dt = -50/\sqrt{2}$.

EXERCISES

1. Water is flowing into a tank of cylindrical shape at the rate of 100 gal. per minute. If the tank is 8 ft. in diameter, find the rate of increase in the height of the water in the tank.

2. A funnel 12 in. across the top and 9 in. deep is being emptied at the rate of 2 cu. in. per minute. How fast does the surface of the liquid fall?

3. If water flows from a hole in the bottom of a cylindrical can of radius r into another can of radius r', compare the vertical rates of rise and fall of the two water surfaces.

4. If a funnel is 12 in. wide and 9 in. deep and liquid flows from it at the rate of 5 cu. in. per minute, determine the time-rate of fall of the surface of the liquid.

5. Compare the vertical rates of the two liquid surfaces when water drains from a conical funnel into a cylindrical bottle. Compare the time-rate of flow from the funnel with the time-rate of the decrease of the wet perimeter.

6. If a wheel of radius R is turned by rolling contact with another wheel of radius R', compare their angular speeds and accelerations.

7. If the surface s of a cube increases at a given rate k (in square inches per second), what is the rate of increase of the volume?

8. If a point moves on a circle so that the arc described in time t is $s = t^2 - 1/t^2 + 1$, find the angular speed and acceleration of the radius drawn to the moving point.

9. A point moves along the parabola $y = 2x^2 - x$ in such a manner that the speed of the abscissa x is 4 ft./sec. Find the general expression for the speed of y; and find its value when $x = 1$; when $x = 3$.

10. In Ex. 9, find the horizontal and vertical accelerations, the total speed, the tangential acceleration, and the total acceleration.

11. A point moves on the cubical parabola $y = x^3$ in such a way that the horizontal speed is 10 ft./sec. Find the vertical speed when $x = 6$.

12. In Ex. 11, find the horizontal, vertical, tangential, and total accelerations.

13. If a person walks along a sidewalk at the rate of 4 ft. per sec. toward the gate of a yard, how fast is he approaching a house in the yard which is 50 ft. from the gate in a line perpendicular to the walk, when he is 100 ft. from the gate? When 10 ft. from the gate?

14. Two ships start from the same point at the same time, one sailing due east at 10 knots an hour, the other due northwest at 12 knots an hour. How fast are they separating at any time? How fast, if the first ship starts an hour before the other?

15. If a ladder 13 ft. long rests against the side of a room, and its foot moves along the floor at a uniform rate of 2 ft./sec., how fast is the top descending when it is 5 ft. above the floor? When the top is 1 inch from the floor?

16. If the radius of a sphere increases as the square root of the time, determine the time-rate of change of the surface and that of the volume; the acceleration of the surface and that of the volume.

17. If a projectile is fired at an angle of elevation α and with muzzle velocity v_0, its path (neglecting the resistance of the air) is the parabola

$$y = x \tan \alpha - \frac{gx^2}{2\, v_0^2 \cos^2 \alpha},$$

x being the horizontal distance and y the vertical distance from the point of discharge. Draw the graph, taking $g = 32$, $\alpha = 20°$, $v_0 = 2000$ ft./sec.

Calculate dy in terms of dx. In what direction is the projectile moving when $x = 5000$ ft., 10,000 ft., 20,000 ft.? How high will it rise?

18. If $p \cdot v = k$, compare dp/dt and dv/dt in general; compare d^2p/dt^2 and d^2v/dt^2.

19. If $p \cdot v^n = k$, compare dp/dt and dv/dt. [For air, in rapid compression, $n = 1.41$, nearly.]

20. If q is the quantity of one product formed in a certain chemical reaction in time t, it is known that $q = ck^2t/(1 + ckt)$. The time-rate of change of q is called the *speed* v of the reaction. Show that

$$v = \frac{ck^2}{(1 + ckt)^2} = c(k - q)^2.$$

Show also that the *acceleration* α of the reaction is

$$\alpha = -\frac{2\,c^2k^3}{(1 + ckt)^3} = -2\,c^2(k - q)^3.$$

CHAPTER VII

REVERSAL OF RATES — INTEGRATION

48. Reversal of Rates. Up to this point, we have been engaged in finding rates of change of given functions. Often, the rate of change is known and the values of the quantity which changes are unknown; this leads to the problem of this chapter: *to find the amount of a quantity whose rate of change is known.*

Simple instances of this occur in every one's daily experience. Thus, if the rate r (in cubic feet per second) at which water is flowing into a tank is known, the total amount A (in cubic feet) of water in the tank at any time can be computed readily, — at least if the amount originally in the tank is known:

$$A = r \cdot t + C,$$

where t is the time (in seconds) the water has run, and C is the amount originally in the tank, *i.e.* C is the value of A at the time when $t = 0$.

If a train runs at 30 miles per hour, its total distance d, from a given point on the track, is

$$d = 30 \cdot t + C,$$

where t is the time (in hours) the train has run, and C is the original distance of the train from that point, *i.e.* C is the value of d when $t = 0$. (Notice that by regarding d as negative in one direction, this result is perfectly general; C may also be negative.)

If a man is saving \$100 a month, his total means is $100 \cdot n + C$, where n is the number of months counted, and C is his means at the beginning; *i.e.* C is his means when $n = 0$.

If the cost for operating a printing press is 0.01 ct. per sheet the total expense of printing is

$$T = 0.01 \cdot n + C$$

where n is the number of copies printed, and where C is the first cost of the machine; *i.e.* C is the value of T when $n = 0$.

49. Principle Involved. Such simple examples require no new methods; they illustrate excellently the following fact:

The total amount of a variable quantity y at any stage is determined when its rate of increase and its original value C are known.

We shall see that this remains true even when the rate itself is variable.

50. Illustrative Examples. The rate $R(x)$ at which any variable y increases with respect to an independent variable x is the *derivative* dy/dx; hence the general problem of §§ 48–49 may be stated as follows: *given the derivative* dy/dx, *to find* y *in terms of* x.

In many instances our familiarity with the rules for obtaining rates of increase (*differentiation*) enables us to set down at once a function which has a given rate of increase.

EXAMPLE 1. Thus, in each of the examples given in § 48, the rate is constant; using the letters of this article:

$$\frac{dy}{dx} = R(x) = k,$$

where k is a known fixed number; it is obvious that a function which has this derivative is

$$(A) \qquad y = kx + C,$$

where C is any constant chosen at pleasure.

While the examples of § 48 can all be solved very easily without this new method, for those which follow it is at least very convenient. The value of C in any given example is found as in § 48; it represents the value of y when $x = 0$.

EXAMPLE 2. Given $dy/dx = x^2$, to find y in terms of x.

Since we know that $d(x^3)/dx = 3x^2$, and since multiplying a function by a number multiplies its derivative by the same number, we should evidently take:

$$y = \frac{x^3}{3}, \text{ or else } y = \frac{x^3}{3} + C; \left[\text{check: } d\left(\frac{x^3}{3} + C\right) = x^2\,dx\right],$$

where C is some constant. As in § 48, some additional information must be given to determine C. In a practical problem, such as Ex. 3, below, information of this kind is usually known.

EXAMPLE 3. A body falls from a height 100 ft. above the earth's surface; given that the speed is $v = -gt$, find its distance from the earth in terms of the time t.

Let s denote the distance (in feet) of the body from the earth; we are given that

$$(1) \qquad v = \frac{ds}{dt} = -gt, \quad \text{or} \quad ds = vdt = -gt\,dt,$$

which is negative since s is decreasing. We know that $d\,(t^2) = 2\,t\,dt$; hence it is evident that we should take:

$$(2) \qquad s = -\frac{g}{2}t^2 + C; \ [\text{check: } ds = -gt\,dt].$$

As the body starts to fall, $t = 0$ and $s = 100$; substituting these values in (2) we find $100 = 0 + C$, or $C = 100$. Hence we have

$$s = -\frac{g}{2}t^2 + 100.$$

EXAMPLE 4. Given $dy/dx = x^n$, to find y in terms of x.

Since we know that $d(x^{n+1}) = (n+1)\,x^n\,dx$, we should take

$$(B) \qquad y = \frac{1}{n+1}x^{n+1} + C; \ [\text{check: } dy = x^n\,dx].$$

Since the rule for differentiation of a power is valid (§ 21, p. 34) for all positive and negative values of n, the formula (B) holds for all these values of n *except* $n = -1$; when $n = -1$ the formula (B) can not be used because the denominator $n + 1$ becomes zero.

Special cases:

$$n = 1, \ \frac{dy}{dx} = x, \ y = \frac{1}{2}x^2 + C; \ \text{check: } d\left(\frac{1}{2}x^2\right) = x\,dx.$$

$$n = 0, \ \frac{dy}{dx} = 1, \ y = x + C; \ \text{check: } d\,(x) = 1\cdot dx.$$

$$n = \frac{1}{2}, \ \frac{dy}{dx} = x^{1/2}, \ y = \frac{2}{3}x^{3/2} + C; \ \text{check: } d\left(\frac{2}{3}x^{3/2}\right) = x^{1/2}\,dx.$$

$$n = -2, \ \frac{dy}{dx} = x^{-2}, \ y = -x^{-1} + C; \ \text{check: } d\,(-1\,x^{-1}) = x^{-2}\,dx.$$

Notice that these include $\sqrt{x}\ (= x^{1/2})$, $1/x^2\ (= x^{-2})$, etc.; other special cases are left to the student.

EXAMPLE 5. Given $dy/dx = x^3 + 2x^2$, to find y in terms of x.

Since $d(x^4)/dx = 4x^3$ and $d(x^3)/dx = 3x^2$, and since the derivative of a sum of two functions is equal to the sum of their derivatives, it is evident that we should write *

$$y = \frac{x^4}{4} + \frac{2x^3}{3} + C.$$

The check is

$$\frac{dy}{dx} = \frac{d}{dx}\left(\frac{x^4}{4} + \frac{2x^3}{3} + C\right) = x^3 + 2x^2;$$

such a check on the answer should be made in every exercise.

In general, as in this example, if the given rate of increase (derivative) is the sum of two parts, the answer is found by adding the answers which would arise from the parts taken separately, since the sum of the derivatives of two variables is always the derivative of their sum.

EXERCISES

Determine functions whose derivatives are given below; do not forget the additive constant; check each answer.

1. $\frac{dy}{dx} = 4x.$ **2.** $\frac{dy}{dx} = -5x.$ **3.** $\frac{dy}{dx} = 3x^2.$ **4.** $\frac{dy}{dx} = 2.$

5. $\frac{dy}{dx} = -6x^2.$ **6.** $\frac{dy}{dx} = -10x^5.$ **7.** $\frac{dy}{dx} = -x^4.$ **8.** $\frac{dy}{dx} = .01x^8.$

In the following exercises, remember that the derivative of a sum is the sum of the derivatives of the several terms; proceed as above.

9. $\frac{dy}{dx} = 4 + 5x^2.$ **10.** $\frac{dy}{dx} = 4x^2 - 2x + 3.$ **11.** $\frac{ds}{dt} = t^3 - 4t + 7.$

12. $\frac{dy}{dx} = 3x^5 - 8x^4.$ **13.** $\frac{dy}{dx} = ax + b.$ **14.** $\frac{ds}{dt} = at^2 + bt + c.$

15. $\frac{dy}{dx} = .006x^2 - .004x^3 + .015x^4.$ **16.** $\frac{ds}{dt} = -t^6 + 5t^4 - 6t^2 + 2.$

17. $\frac{dy}{dx} = x^{-3}.$ **18.** $\frac{ds}{dt} = t^2 + 1/t^2.$ **19.** $\frac{dv}{dt} = 3t^{-2} + 4t^{-3}.$

20. $\frac{dy}{dx} = x^{2/3}.$ **21.** $\frac{dy}{dx} = 2x^{1/2} - 3x^{-1/2}.$ **22.** $\frac{dp}{dv} = kv^{-2.41}.$

* In all the Examples of this paragraph, we have had an equation which involves dy/dx; such an equation is often called a ***differential equation***, because it contains differentials. See also Chapter XIX.

51. Integral Notation. If the rate of increase $dy/dx = R(x)$ of one variable y with respect to another variable x *is given, a function* $y = I(x)$ *which has precisely this given rate of increase is called an* ***indefinite integral**** *of the rate* $R(x)$, *and is represented by the symbol* †

$$(1) \qquad I(x) = \int R(x)\,dx;$$

that is,

$$(2) \quad \textit{if} \quad \frac{d}{dx}[I(x)] = R(x), \qquad \textit{then} \quad I(x) = \int R(x)\,dx,$$

or, what amounts to the same thing,

$$(3) \quad \textit{if} \quad d[I(x)] = R(x)\,dx, \qquad \textit{then} \quad I(x) = \int R(x)\,dx.$$

The results of Examples 1, 2, 3, § 50, written with the new symbol, are, respectively,

$$[A] \qquad \int k\,dx = kx + C.$$

$$\int x^2\,dx = x^3/3 + C.$$

$$s = \int v\,dt + C = \int -gt\,dt + C = -gt^2/2 + C.$$

The first equation of Example 3 holds in general:

$$[\mathrm{I}] \qquad s = \int v\,dt + C, \text{ since } \frac{ds}{dt} = v.$$

* The common English meaning of the word *integrate* is "to make whole again," "to restore to its entirety," "to give the sum or total." See any dictionary, and compare §§ 48–49.

To integrate a rate $R(x)$ is to find its *integral;* the process is called integration. Often the rate function $R(x)$ which is integrated is called the integrand; thus the first part of equation (2) may be read: "*the derivative of the integral is the integrand.*" This is the property used in checking answers.

The first equation in (2) and the first in (3) are *differential* equations.

† Note that dx is *part of the symbol.* As a blank symbol, it is $\int$ (blank) $dx;$ the function $R(x)$ to be integrated (*i.e.* the integrand) is inserted in place of the blank. The origin of this symbol is explained in § 120.

The result obtained in (*B*), Example 4, § 50, gives

$$[B] \qquad \int x^n\,dx = \frac{x^{n+1}}{n+1} + C,\ n \neq -1,$$

for all positive and negative integral and fractional values of n *except* $n = -1$, for which see § 65.

As examples of the many special cases, we write:

$$n = 1, \qquad \int x\,dx = \frac{x^2}{2} + C.$$

$$n = 0, \qquad \int x^0\,dx = \int 1\,dx = \int dx = x + C.$$

$$n = \frac{1}{2}, \qquad \int x^{1/2}\,dx = \int \sqrt{x}\,dx = \tfrac{2}{3}x^{3/2} + C = \tfrac{2}{3}\sqrt{x^3} + C.$$

$$n = -2, \qquad \int x^{-2}\,dx = \int \frac{1}{x^2}\,dx = -x^{-1} + C = -\frac{1}{x} + C.$$

$$n = -\frac{1}{3}, \qquad \int x^{-1/3}\,dx = \int \frac{1}{\sqrt[3]{x}}\,dx = \tfrac{3}{2}x^{2/3} + C = \tfrac{3}{2}\sqrt[3]{x^2} + C.$$

From Example 5:

$$\int (x^3 + 2x^2)\,dx = \int x^3\,dx + \int 2x^2\,dx = \frac{x^4}{4} + \frac{2x^3}{3} + C.$$

The general principle used in this example is that the *integral of a sum of two functions is the sum of their integrals:*

$$[C] \qquad \int [R(x) + S(x)]\,dx = \int R(x)\,dx + \int S(x)\,dx,$$

which is true because the derivative of the sum $R(x) + S(x)$ is the sum of the derivatives:

$$d[R + S]/dx = dR/dx + dS/dx.$$

The rules (*A*), (*B*), (*C*) are sufficient to integrate a large number of functions, including certainly all *polynomials* in x.

EXERCISES

1. Express the value of y if $dy/dx = 4x^2 + 3x$ by means of the new sign $\int(-)\,dx$. Then find y. Check the answer by differentiation.

Proceed as in Ex. 1 if $y\ dy/dx$ has one of the following values:

2. x^3. **4.** x^{-4}. **6.** $x^3 - 2$. **8.** $x^2 + 3x - 4$. **10.** $mx - n$.

3. x^{-3}. **5.** $4x + 5$. **7.** 9. **9.** $x^3 - x^4$. **11.** $x + \sqrt{x}$.

In the following exercises express the given function as a sum of powers of x; then proceed as above.

12. $x^2(1 + x)$. **16.** $(1 + x^3)(1 - x^3)$. **20.** $(1 - x^2)(1 + x^{-2})$.

13. $(x^3 + 5x^2) \div x^2$. **17.** $(3 - x)(5 + 2x)$. **21.** $x^{3/2}(x - x^2)$.

14. $3(x - 2)^2$. **18.** $x^{1/2}(2 - x)$. **22.** $(x^3 - 2x^2 + x)^{1/2}$.

15. $3x^3(4 - 3x)$. **19.** $(3 - 2x)\sqrt{x}$. **23.** $(1 + \sqrt[3]{x})^2$.

Evaluate the following integrals:

24. $\int x^{-5}\,dx$. **29.** $\int\left(\frac{1}{v^2} + \frac{1}{v^3}\right)dv$. **34.** $\int 12\,t^{-7/2}\,dt$.

25. $\int t^{3/4}\,dt$. **30.** $\int(6u^{-3} - 7u^{-4})\,du$. **35.** $\int 3\sqrt[4]{y^{-3}}\,dy$.

26. $\int 5\,s^{-5}\,ds$. **31.** $\int(z^{3/5} + z^{-3/5})\,dz$. **36.** $\int(5/\sqrt{u^3})\,du$.

27. $\int(2\sqrt[3]{u} - u^{-1/2})\,du$. **32.** $\int(\sqrt[3]{y^2} - 4y^{-5})\,dy$. **37.** $\int(\sqrt[3]{u})^5\,du$.

28. $\int 3\,r^{-2/3}\,dr$. **33.** $\int(y^{10/3} + 2y^{4/3})\,dy$.

Integrate the following expressions, making use of the principle of Exs. 12–23.

38. $\int(1 - t)^2\,dt$. **44.** $\int\sqrt{x}\,(a + bx)\,dx$.

39. $\int x(1 + \sqrt{x})\,dx$. **45.** $\int x^n(a + bx)\,dx$.

40. $\int s(1 - \sqrt{s})^2\,ds$. **46.** $\int(a + bx)^2\,dx$.

41. $\int t^2(1 - t^2)\,dt$. **47.** $\int(t^{2.5} - 2)\,t^{-5}\,dt$.

42. $\int x^{-4}(1 + x + x^2)\,dx$. **48.** $\int x^{1.4}(1 + x^2)^2\,dx$.

43. $\int x(a + bx)\,dx$. **49.** $\int\sqrt{t(1 + 2t^2)^2}\,dt$.

52. Fundamental Theorem. If $dy/dx = 2x$, the answers $y = x^2, y = x^2 + 5, y = x^2 + C$ are all correct. To decide which one is wanted, additional information is needed. However, except for the additive constant C, all answers coincide. For practical purposes, there is but *one* answer. Stated precisely, this is the ***fundamental theorem of integral calculus:***

If the rate of increase

$$\frac{dy}{dx} = R(x) \tag{1}$$

of a variable quantity y which depends on x is given, then y is determined as a function of x, I (x), except for a constant term:

$$y = \int R(x)\,dx + C = I(x) + C. \tag{2}$$

53. Calculation by Integrals. In applications, we often care little about the actual total; it is rather the difference between two values which is important.

Thus, in a motion, we care little about the real total distance a body has traveled; it is rather the distance it has traveled *between two given instants.*

If a body falls from any height, the distance it falls is (Ex. 3, p. 81)

$$s = v\,dt + C = \int gt\,dt + C = \frac{gt^2}{2} + C,$$

where s is counted downwards.

The value of s when $t = 0$ is $s]_{t=0} = C$; the value of s when $t = 1$ is $s]_{t=1} = g/2 + C$. The distance traversed *in the first second* is found by subtracting these values:

$$s\Big]_{t=0}^{t=1} = s\Big]_{t=1} - s\Big]_{t=0} = \left(\frac{g}{2} + C\right) - C = \frac{g}{2} = 16.1 \text{ ft.},$$

where $s]_{t=0}^{t=1}$ means the space passed over between the times $t = 0$ and $t = 1$.

In this calculation, we care little about where s is counted from; or its *total* value. The result is the same for all bodies dropped from any height.

Likewise, the space passed over between the times $t = 2$ and $t = 5$ is

$$s\Big]_{t=2}^{t=5} = s\Big]_{t=5} - s\Big]_{t=2} = \left(\frac{g\cdot 25}{2} + C\right) - \left(\frac{g\cdot 4}{2} + C\right)$$
$$= \frac{g\cdot 25}{2} - \frac{g\cdot 4}{2} = g\cdot\frac{21}{2} = 338 \text{ (ft.)}.$$

In general the distance traversed between the times $t = a$ and $t = b$ is

$$s\Big]_{t=a}^{t=b} = s\Big]_{t=b} - s\Big]_{t=a} = \left(g\frac{b^2}{2} + C\right) - \left(g\frac{a^2}{2} + C\right) = g\frac{b^2}{2} - g\frac{a^2}{2} = \frac{g}{2}(b^2 - a^2).$$

54. Definite Integrals. The advantage realized in the example of § 53 in eliminating C can be gained in all problems.

The numerical value of the total change in a quantity between two values of x, $x = a$ and $x = b$, can be found if the rate of change $dy/dx = R(x)$ is given. For, if

$$y = I(x) = \int R(x)\,dx + C,$$

the value of y for $x = a$ is

$$y\Big]_{x=a} = I(a) = \left[\int R(x)\,dx\right]_{x=a} + C,$$

and the value of y for $x = b$ is

$$y\Big]_{x=b} = I(b) = \left[\int R(x)\,dx\right]_{x=b} + C.$$

The total change in y between the values $x = a$ and $x = b$ is

$$y\Big]_{x=a}^{x=b} = y\Big]_{x=b} - y\Big]_{x=a} = I(b) - I(a)$$
$$= \left[\int R(x)\,dx\right]_{x=b} - \left[\int R(x)\,dx\right]_{x=a}.$$

This difference, found by subtracting the values of the indefinite integral at $x = a$ from its value at $x = b$, is called the ***definite integral*** *of $R(x)$ between $x = a$ and $x = b$; and is denoted by the symbol:*

$$\int_{x=a}^{x=b} R(x)\,dx = \left[\int R(x)\,dx\right]_{x=b} - \left[\int R(x)\,dx\right]_{x=a}.$$

It should be noticed that, in subtracting, the unknown constant C has disappeared completely; this is the reason for calling this form *definite*.

EXAMPLE 1. Given $dy/dx = x^3$, find the total change in y from $x = 1$ to $x = 3$.

Since

$$y = \int x^3\,dx = x^4/4 + C,$$

it follows that

$$y\Big]_{x=1}^{x=3} = y\Big]_{x=3} - y\Big]_{x=1} = \frac{x^4}{4}\Big]_{x=3} - \frac{x^4}{4}\Big]_{x=1} = 20.$$

Interpreted as a problem in motion, where x means time and y means distance, this would mean: the total distance traveled by a body between the end of the first second and the end of the third second, if its speed is the cube of the time, is twenty units.

Interpreted graphically, a curve whose slope m is given by the equation $m = x^3$, rises 20 units between $x = 1$ and $x = 3$. The equation of the curve is $y = x^4/4 + C$.

EXERCISES

1. If water pours into a tank at the rate of 300 gal. per minute, how much enters in the first ten minutes? how much from the beginning of the fifth minute to the beginning of the tenth minute?

2. If a train is moving at a speed of 30 mi. per hour, how far does it go in two hours? Does this necessarily mean the distance from its last stop?

3. If a train leaves a station with a variable speed $v = t/2$ (ft./sec.), find s in terms of t. How far does the train go in the first ten seconds? How far from the beginning of the fifth to the beginning of the tenth second?

4. A falling body has a speed $v = gt$, where t is measured from the instant it starts. How far does it go in the first four seconds? How far between the times $t = 3$ and $t = 9$?

5. A wheel rotates with a variable speed (radians/sec.) $\omega = t^2/100$. How many revolutions does it make in the first fifteen seconds? How many between the times $t = 1$ and $t = 10$?

From the following rates of change determine the total change in the functions between the limits indicated for the independent variable. Interpret each result geometrically and as a problem in motion, and write your work in the notation used in the text.

6. $\dfrac{dy}{dx} = x$, $x = 2$ to $x = 4$.

7. $\dfrac{dy}{dx} = \dfrac{1}{5}x^2$, $x = -2$ to $x = 2$.

8. $\dfrac{dy}{dx} = \dfrac{x^3}{12}$, $x = -4$ to $x = 4$.

9. $\dfrac{dy}{dx} = 2 - x^2$, $x = 0$ to $x = 10$.

10. $\dfrac{ds}{dt} = \dfrac{1}{t^2}$, $t = 1$ to $t = 10$.

11. $\dfrac{ds}{dt} = \dfrac{t^4 - 3}{t^2}$, $t = 1$ to $t = 3$.

12. $\dfrac{dv}{dt} = \dfrac{(1+t)^2}{t^{3/2}}$, $t = 4$ to $t = 9$.

13. $\dfrac{dv}{dt} = \dfrac{2t^{-1} - 6t^{-2}}{t^2}$, $t = 0.1$ to 1.

14. $\dfrac{d\theta}{dt} = \sqrt{t\sqrt{t}}$; $t = 1$ to $t = 16$.

15. $\dfrac{d\theta}{dt} = \dfrac{a^2}{t^2} + \dfrac{a^3}{t^3}$, $t = a$ to $t = 2a$.

Determine the values of the following definite integrals. [In cases where no misunderstanding could possibly arise, only the numerical values of the limits are given. *In every such case, the numbers stated as limits are values of the variable whose differential appears in the integral.*]

16. $\displaystyle\int_{x=0}^{x=2} 3x\,dx$.

17. $\displaystyle\int_{x=-2}^{x=+2} 3x\,dx$.

18. $\displaystyle\int_{x=1}^{x=2} 3x^2\,dx$.

19. $\displaystyle\int_{x=-a}^{x=a} 5x^2\,dx$.

20. $\displaystyle\int_0^9 \sqrt{x}\,dx$.

21. $\displaystyle\int_0^{27} x^{2/3}\,dx$.

22. $\displaystyle\int_{t=3}^{t=7} (1+t)\,dt$.

23. $\displaystyle\int_{t=-2}^{t=0} 3(t^2-1)\,dt$.

24. $\displaystyle\int_{-2}^{3} (1+s+s^2)\,ds$.

25. $\displaystyle\int_1^3 \frac{1+s^4}{s^2}\,ds$.

26. $\displaystyle\int_1^{-8} s^{2/3}(s^2-2s)\,ds$.

27. $\displaystyle\int_{\theta=0}^{\theta=.02} \frac{d\theta}{100}$.

28. $\displaystyle\int_{\theta=10}^{\theta=100} (.01 + .02\,\theta)\,d\theta$.

29. $\displaystyle\int_8^{27} \left(\sqrt[3]{\theta} + \frac{1}{\sqrt[3]{\theta}}\right) d\theta$.

30. $\displaystyle\int_{2.3}^{7.4} v^{-1.41}\,dv$.

31. A stone falls with a speed $v = gt + 10$. Find s in terms of t and find the distance passed over between the times $t = 2$ and $t = 7$.

32. A bullet is fired vertically with a speed $v = -gt + 1500$. How far does it go in ten seconds? How high does it rise? How long is it in the air? Make rough estimates of the answers in advance.

33. For any falling body, j = acceleration = g = const. Find the increase in speed in ten seconds. Does it matter what particular ten seconds are chosen?

34. If, in Ex. 33, the speed is 100 ft./sec. when $t = 5$, what is the speed when $t = 15$? When will the speed be 250 ft./sec.? Express v in terms of t.

55. Area under a Curve. We saw in § 54 that the value of any quantity could be computed if its rate of change could be found. We shall proceed to illustrate this principle by showing how to find the area bounded by any given curve, the x-axis, and any two ordinates of the curve.

Let the equation of the given curve be

(1) $$y = f(x),$$

and let A denote the area $FMQP$ between this curve, the x-axis, a fixed ordinate FP (Fig. 20), and a variable ordinate MQ. Since A will vary as the value of x at M changes, A is a function of x.

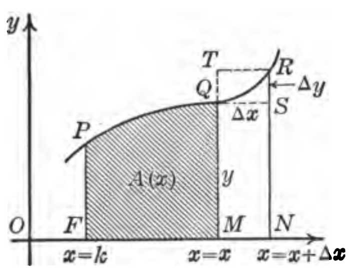

Fig. 20.

If x changes by an amount $\Delta x = MN$, the area A will change by an amount $MNRQ$, which we shall call ΔA. Then it is evident from the figure that if the curve rises from Q to R we shall have

(2) $$\textit{rectangle } MNSQ < \Delta A < \textit{rectangle } MNRT.$$

If the curve falls from Q to R, the inequalities would be reversed. From (2) we have

(3) $$y \cdot \Delta x < \Delta A < (y + \Delta y) \cdot \Delta x.$$

Dividing by Δx, we find

(4) $$y < \frac{\Delta A}{\Delta x} < y + \Delta y.$$

If the curve falls from Q to R, these inequalities would simply be reversed. If we now let Δx approach zero, Δy will also approach zero, and we shall have, in either case,

$$(5) \qquad \frac{dA}{dx} = \lim_{\Delta x \to 0} \frac{\Delta A}{\Delta x} = y = f(x).$$

It follows, by § 54, that the area under the curve (1), between any two fixed ordinates $x = a$ and $x = b$, is given by the formula

$$(6) \qquad A\Big]_{x=a}^{x=b} = \int_{x=a}^{x=b} y\,dx = \int_{x=a}^{x=b} f(x)\,dx.$$

EXAMPLE 1. To find the area under the curve* $y = x^2$ between the points where $x = 0$ and $x = 2$.

We have, by (2)

$$A = \int y\,dx + C = \int x^2 dx + C = \frac{x^3}{3} + C,$$

where A is counted from any fixed back boundary $x = k$ we please to assume, up to a movable boundary $x = x$.

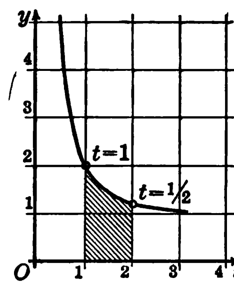

FIG. 21.

The area between $x = 0$ and $x = 2$ is given by subtracting the value of A for $x = 0$ from the value for A for $x = 2$:

$$A\Big]_{x=0}^{x=2} = A\Big]_{x=2} - A\Big]_{x=0} = \int_{x=0}^{x=2} x^2\,dx = \frac{x^3}{3}\Big]_{x=2} - \frac{x^3}{3}\Big]_{x=0} = \frac{8}{3}.$$

Likewise the area under the curve between $x = 1$ and $x = 3$ is

$$A\Big]_{x=1}^{x=3} = \int_{x=1}^{x=3} x^2 dx = \frac{x^3}{3}\Big]_{x=3} - \frac{x^3}{3}\Big]_{x=1} = 8\tfrac{2}{3};$$

and the area under the curve between any two vertical lines $x = a$ and $x = b$ is

$$A\Big]_{x=a}^{x=b} = \int_{x=a}^{x=b} x^2 dx = \frac{x^3}{3}\Big]_{x=b} - \frac{x^3}{3}\Big]_{x=a} = \frac{b^3 - a^3}{3}.$$

* The phrase "the area under the curve" is understood in the sense used in § 55. When the curve is below the x-axis, this area is counted as negative.

If the equation of the curve is given in parameter form

$$\text{(7)} \qquad \begin{cases} x = f(t), \\ y = \phi(t), \end{cases}$$

the equation (5) may be replaced by the equation

$$\text{(8)} \qquad \frac{dA}{dt} = \frac{dA}{dx} \cdot \frac{dx}{dt} = y \cdot \frac{dx}{dt},$$

or

$$\text{(9)} \qquad \frac{dA}{dt} = \phi(t) \cdot \frac{df(t)}{dt},$$

and the formula (6) takes the form

$$\text{(10)} \qquad A\Big]_{t=t_1}^{t=t_2} = \int_{t=t_1}^{t=t_2} y \frac{dx}{dt}\, dt,$$

or

$$\text{(11)} \qquad A\Big]_{t=t_1}^{t=t_2} = \int_{t=t_1}^{t=t_2} \phi(t) \cdot \frac{df(t)}{dt}\, dt,$$

which gives the area above the x-axis, below the curve (7), and between the ordinates of the points at which t has the values t_1 and t_2, respectively.

Example 2. To find the area under the curve whose equations are

$$x = t^2,$$
$$y = \frac{1+t}{t},$$

between the ordinates of the points where $t = 2$ and $t = 3$.

By (11), the required area is

$$A\Big]_{t=2}^{t=3} = \int_{t=2}^{t=3} \frac{1+t}{t} \cdot 2\,t\,dt$$
$$= \int_2^3 (2 + 2\,t)\, dt = 7.$$

[Caution. By calculating in a similar manner the area under the curve from $t = 0$ to $t = 1$ we would find $A\big]_{t=0}^{t=1} = 3$. But this result would require justification by the considerations of § 115, p. 188.]

EXERCISES

Find the area under each of the following curves between the ordinates $x = 0$ and $x = 1$; between $x = 1$ and $x = 4$. Draw the graph and estimate the answer in advance.

1. $y = x^2$.	**4.** $y = x^{2/3}$.	**7.** $y = \sqrt{1 + x}$.
2. $y = \sqrt{x}$.	**5.** $y = 1 - x^2$.	**8.** $y = x^2(1 - x)$.
3. $y = x^{3/2}$.	**6.** $y = (1 - x)^2$.	**9.** $y = x(1 - x^2)$.

Find the area under each of the following curves and check graphically when possible.

10. $y = x^3 + 6x^2 + 15x$, $(x = 0 \text{ to } 2;\ x = -2 \text{ to } +2)$.

11. $y = x^{2/3}$, $(x = -1 \text{ to } +1;\ x = -a \text{ to } +a)$.

12. $y = x^2 + 1/x^2$, $(x = 1 \text{ to } 3;\ x = 2 \text{ to } 5;\ x = a \text{ to } b)$.

Find the area under each of the following curves between the ordinates determined by the indicated values of t, and check graphically.

13. $x = t + 1$, $y = t - 1$; $t = 0$ to 5.

14. $x = (t - 1)/t$, $y = t^3/8$; $t = 2$ to 4.

15. $x = 2t$, $y = 3\sqrt{t}$; $t = 0$ to 4.

16. $x = 1 + \sqrt{t}$, $y = 2t^2$; $t = 0$ to 9.

17. $x = (1 + t)^2$, $y = (1 - t)^2$; $t = 1$ to 2.

18. $x = 1 - t$, $y = \sqrt{1 + t}$; $t = -1$ to 3.

19. $x = \sqrt{t + 1}$, $y = \sqrt{t^2 - 1}$; $t = 1$ to 5.

20. Show the area A bounded by a curve $x = \phi(y)$, the y-axis, and the two lines $y = a$ and $y = b$ is

$$A = \int_{y=a}^{y=b} \phi(y)\,dy.$$

21. Calculate the area between the y-axis, the curve $x = y^2$, and the lines $y = 0$ and $y = 1$. Compare this answer with that of Ex. 14.

22. Find the area between the curve $y = x^3$ and each of the axes separately, from the origin to a point (k, k^3). Show that their sum is k^4.

56. Volume of a Solid of Revolution. Let us next consider the volume of the solid of revolution which is described when the area $MNLK$ (Fig. 22) under the curve $y = f(x)$ from $x = a$ to $x = b$ is revolved about the x-axis. Any section of this solid perpendicular to the x-axis will be a circle.

Let us denote by V the volume from $x = a$ to $x = x$, and by ΔV the increase in this volume as x increases to $x + \Delta x$. The radius of the circular section at any point is the ordinate

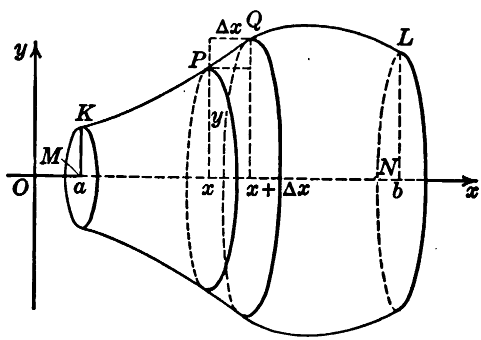

FIG. 22.

y of the curve. Hence the area of the section is πy^2. If the curve is rising steadily from P to Q, it is evident that

(1) $$\pi y^2 \cdot \Delta x < \Delta V < \pi (y + \Delta y)^2 \cdot \Delta x.$$

Dividing by Δx, we have

(2) $$\pi y^2 < \frac{\Delta V}{\Delta x} < \pi (y + \Delta y)^2.$$

If the curve is falling, these inequalities are reversed. If we now let Δx approach zero, Δy will approach zero, and we shall have, in either case,

(3) $$\frac{dV}{dx} = \lim_{\Delta x \to 0} \frac{\Delta V}{\Delta x} = \pi y^2.$$

It follows, by § 54, that the volume of the solid of revolution from $x = a$ to $x = b$, is given by the formula

$$(4) \qquad V\Big]_{x=a}^{x=b} = \int_{x=a}^{x=b} \pi y^2\,dx = \int_{x=a}^{x=b} \pi\{f(x)\}^2\,dx.$$

Similarly, the volume V of a solid of revolution formed by revolving a curve $x=\phi(y)$ around the y-axis satisfies the relations

$$(5) \qquad \frac{dV}{dy} = \pi x^2, \qquad V\Big]_{y=c}^{y=d} = \int_{y=c}^{y=d} \pi x^2\,dy.$$

EXAMPLE. Find the volume generated when the area under the curve $y = 1 - x^2$ from $x = -1$ to $x = +1$ revolves about the x-axis.

From the symmetry of the figure, we see that the total volume required is twice the volume generated by the area from $x = 0$ to $x = 1$. Hence

$$\begin{aligned} V\Big]_{x=-1}^{x=1} &= 2\int_0^1 \pi y^2\,dx \\ &= 2\pi\int_0^1 (1-x^2)^2\,dx \\ &= 2\pi\int_0^1 (1-2x^2+x^4)\,dx \\ &= 2\pi\left(x - \frac{2x^3}{3} + \frac{x^5}{5}\right)\Big]_0^1 \\ &= 2\pi\left(1 - \frac{2}{3} + \frac{1}{5}\right) = \frac{16\pi}{15}. \end{aligned}$$

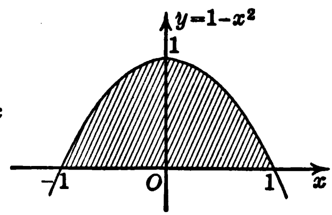

FIG. 23.

57. Volume of a Frustum of a Solid. A frustum of a solid is the portion of that solid contained between two parallel planes. The solid itself, between the limiting parallel planes, may be thought of as generated by the motion of the cross-section parallel to these planes from one extremity to the other, if the shape of the cross-section is supposed to vary in the correct manner during the motion. Thus, a frustum of a circular cone may be generated by the motion of a circle which remains parallel to its original position, if

the radius of the circle steadily increases (or diminishes) during the motion.

In Fig. 24, let s denote the distance along a line AB perpendicular to the variable cross-section, measured from some fixed point A. Let V denote the volume of the solid from $s = a$ to $s = s$, and let ΔV denote the increase in volume as s changes to $s + \Delta s$. Let A_s denote the area of the cross-section at the position $s = s$, and let ΔA denote the increase in A_s as s changes from s to $s + \Delta s$. Then, if A_s increases as s increases, we shall have

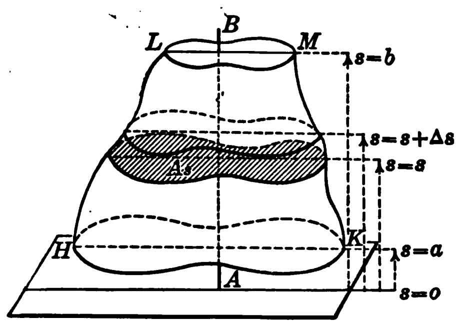

FIG. 24.

(1) $$A_s \cdot \Delta s < \Delta V < (A_s + \Delta A) \cdot \Delta s.$$

This inequality will be reversed if A_s decreases. Dividing by Δs, and then allowing Δs to approach zero, ΔA will also approach zero, and we shall have

(2) $$\frac{dV}{ds} = \lim_{\Delta s \to 0} \frac{\Delta V}{\Delta s} = A_s,$$

whence, by § 54, the volume of the entire frustum from $x = a$ to $x = b$ is given by the formula

(3) $$V\Big]_{s=a}^{s=b} = \int_{s=a}^{s=b} A_s \, ds$$

The formulas (2) and (3) show that the rate of change of the volume with respect to the distance s is equal to the area of the variable cross-section, and that the volume of

the entire frustum is obtained by integrating the area of the cross-section with respect to s. The formulas of § 56 are special cases of the formula (3).

EXAMPLE. A circle moves with its center on a given straight line, and its plane perpendicular to that line. Its radius is proportional to the square of the distances of its center from a fixed point O of the line. Find the volume of the frustum of the solid generated as the circle moves from $s = a$ to $s = b$.

If s denotes the distance from the fixed point O to the center of the circle, the radius of the circle, which is to vary as the square of s, must be $r = ks^2$, where k is a constant. Hence the area of the circle is

$$A_s = \pi r^2 = \pi k^2 s^4.$$

Then the volume of the frustum from $s = a$ to $s = b$ is

$$V\Big]_{s=a}^{s=b} = \int_a^b \pi k^2 s^4\,ds = \pi k^2 \int_a^b s^4\,ds$$
$$= \pi k^2 \left(\frac{s^5}{5}\right)\Big]_a^b = \frac{1}{5}\pi k^2(b^5 - a^5).$$

EXERCISES

Find the volumes formed by revolving each of the following curves about the x-axis, between $x = 0$ to $x = 2$; between $x = -1$ to $x = +1$.

1. $y = x^3$.
2. $y = x^2 - 1$.
3. $y = x^3 - x$.
4. $y = (1 + x)^2$
5. $y^2 = x + 2y$.
6. $\sqrt{x+1} + \sqrt{y} = 4$.

Proceed similarly for each of the following curves, between $x = 1$ and $x = 3$; between $x = a$ and $x = b$.

7. $y = \dfrac{1 + x^2}{x^2}$.
8. $xy = 1 + x^2$.
9. $x^4 - x^2y^2 = 1$.

Find the volumes formed by revolving each of the following curves about the y-axis, between $y = 0$ and $y = 2$.

10. $x = y^3$.
11. $x^2 = y^3$.
12. $x = 4y^2 - y^3$.
13. $x^2 + y^4 = 81$.
14. $x = y^2 - y$.
15. $x = y^{1/2} + y^{1/4}$.

16. Find by integration the volume of a frustum of a cone of height h, if the radii of the two bases are, respectively, r and R.

17. Find the volume of the paraboloid of revolution formed by revolving $y^2 = 4x$ about the x-axis, between $x = 0$ and $x = 4$; between $x = 1$ and $x = 5$; between $x = a$ and $x = b$.

18. Find the volume of a sphere by the formula of § 56.

19. Find the volume of the ellipsoid of revolution formed by revolving an ellipse (1) about its major axis; (2) about its minor axis.

20. Find the volume of the portion of the hyperboloid of revolution formed by revolving about the y-axis the portion of the hyperbola $x^2 - y^2 = 1$ between $y = 0$ and $y = 2$.

21. Find the volume of the portion of the hyperboloid of revolution formed by revolving $x^2 - y^2 = 1$ about the x-axis, between $x = 1$ and $x = 3$.

22. Find the volume generated by a square of variable size perpendicular to the x-axis, which moves from $x = 0$ to $x = 5$, if the length of the side of the square is (1) proportional to x; (2) equal to x^2.

23. Find the volume generated by a variable equilateral triangle perpendicular to the x-axis, which moves from $x = 0$ to $x = 2$, if a side of the triangle is (1) equal to x^2; (2) proportional to $2 - x$.

24. Find the volume generated by a variable circle which moves in a direction perpendicular to its own plane through a distance 10, if the radius varies as the cube of the distance from the original position.

25. Find the mass of a right circular cylinder of variable density, if the density varies (1) directly as the distance from the base; (2) inversely as the square root of the distance from the base.

CHAPTER VIII

LOGARITHMS — EXPONENTIAL FUNCTIONS

58. Necessity of Operations on Logarithms. The necessity for the introduction of logarithms in the Calculus depends not only on their own general importance, but also upon the fact that *integrals of algebraic functions may involve logarithms.*

Thus, in § 51, in the case $n = -1$ the integral $\int x^n\,dx$ could not be found, although the integrand $1/x$ is comparatively simple. We shall see that this integral, $\int x^{-1}\,dx$, results in a *logarithm.* We shall see also in § 68 that numerous cases arise in science in which the rate of variation of a function $f(x)$ is precisely $1/x$.

59. Properties of Logarithms. The ***logarithm*** L of a number N to any base B is defined by the fact that the two equations

(1) $$N = B^L, \qquad \log_B N = L$$

are equivalent. Thus if $L = \log_B N$ and $l = \log_B n$, the identity $B^L \cdot B^l = B^{L+l}$ is equivalent to the rule

(2) $$\log_B (N \cdot n) = \log_B N + \log_B n,$$

where n and N are any two numbers. Likewise $B^L \div B^l = B^{L-l}$ gives

(3) $$\log_B (N \div n) = \log_B N - \log_B n;$$

and $(B^L)^n = B^{Ln}$ becomes

(4) $$\log_B N^n = n \log_B N,$$

where n may have any value whatever.

The relations (1), (2), (3), (4), are the fundamental relations for logarithms.

60. Computations. Graphs. To draw the graph of the equation

(1) $$y = \log_B x,$$

for any fixed value of B, we may write the equation in the form

(2) $$x = B^y.$$

To compute the value of x when y is given, we take the common logarithm of both sides of (2):

(3) $$\log_{10} x = \log_{10} B^y = y \cdot \log_{10} B,$$

by (4) § 59. But since $y = \log_B x$, we have

(4) $$\log_{10} x = \log_B x \cdot \log_{10} B,$$

or

(5) $$\log_B x = \log_{10} x \div \log_{10} B.$$

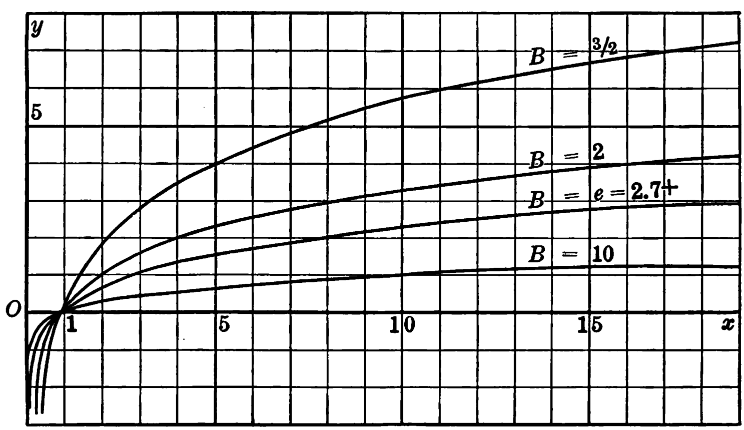

FIG. 25.

The relations (4) and (5) enable us to compute logarithms to any base quickly by means of a table of common logarithms. The graphs of (1) for several values of B are shown in Fig. 25.

The relation (3) enables us to compute fractional powers of any base. For, if B and y are given, as in (2), x may be found from (3) by means of a table of common logarithms.

Similarly, if we take the logarithms of both sides of (2) with respect to any other base b, we find the corresponding relations

$$(4)' \qquad \log_b x = \log_B x \cdot \log_b B,$$

$$(5)' \qquad \log_B x = \log_b x \div \log_b B.$$

If we set $x = b$ in (4)′ and (5)′, since $\log_b b = 1$, we find

$$(6) \qquad \log_B b \cdot \log_b B = 1 \text{ and } \log_B b = 1 \div \log_b B.$$

EXERCISES

1. Find the value of 10^x when $x = 3;\ 0;\ 1.6;\ 2.7;\ -1;\ -1.9;\ 0.43$.

2. Plot the curve $y = 10^x$ carefully, using several fractional values of x.

3. Plot the curve $y = \log_{10} x$ by direct comparison with the figure of Ex. 2. Plot it again by use of a table of logarithms.

Plot the graph of each of the following functions.

4. $\log_{10} x^3$. **5.** $\log_{10} \sqrt[3]{x}$. **6.** $\log_{10} (1/x^2)$. **7.** $\log_{10} x^{4/3}$

Do any relations exist between these graphs?

Plot the graph of each of the following functions and explain its relation to graphs already drawn above.

8. $\log_{10} (1 + x)^2$. **9.** $\log_{10} \sqrt[3]{1 + x}$. **10.** $\log_{10} (x \sqrt[3]{1 + x})$.

Plot the graphs of each of the following functions and show the relations between them.

11. $\log_3 x$. **12.** $\log_9 x$. **13.** $\log_3 x^2$. **14.** 3^x.

Show how to calculate most readily the values of the following expressions, and find the numerical value of each one.

15. $\log_{11} 7$. **17.** $\sqrt{(5.4)^{6.2}}$. **19.** $10^{0.5} + 10^{-0.5}$. **21.** $\log_5 100$.

16. $2^{4.53}$. **18.** $\log_{16} 8$. **20.** $2 \log_3 5$. **22.** $10 \log_{10} 9$.

61. Napierian Logarithms. Base *e*. A careful examination of Fig. 25 will convince anyone that there must be a value of B for which the curve $y = \log_B x$ has a slope equal to 1 at $x = 1$. Indeed, the equation (5), § 60, shows that the slope of the curve $y = \log_B x$ can be found by dividing the slope of the curve $y = \log_{10} x$ by $\log_{10} B$. Hence if $\log_{10} B$ is equal to the slope of the curve $y = \log_{10} x$ at the point (1, 0), the slope of the curve $y = \log_B x$ will be 1 at (1, 0).

Let this value of B be denoted by the letter e. Logarithms to the base e are called ***Napierian logarithms,**** or ***natural logarithms***, or ***hyperbolic logarithms***. (See Table V, C.)

62. Differentiation of $\log_e x$. To find the derivative of $\log_e x$, let us write

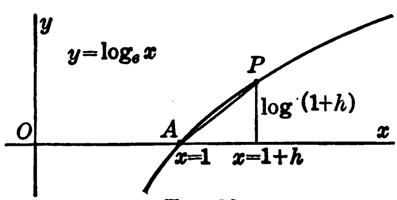

FIG. 26.

$$(1)\qquad y = \log_e x.$$

$$(2)\qquad y + \Delta y = \log_e (x + \Delta x).$$

Hence

$$\Delta y = \log_e (x + \Delta x) - \log_e x = \log_e \left(1 + \frac{\Delta x}{x}\right),$$

and
$$\frac{\Delta y}{\Delta x} = \frac{1}{\Delta x} \log_e \left(1 + \frac{\Delta x}{x}\right) = \frac{1}{x} \cdot \frac{x}{\Delta x} \log_e \left(1 + \frac{\Delta x}{x}\right).$$

Now let $u = \Delta x / x$, so that we may write

$$\frac{\Delta y}{\Delta x} = \frac{1}{x} \cdot \frac{\log_e (1 + u)}{u}.$$

But the fraction $\{\log_e (1 + u)\}/u$ is simply the slope of the secant AP of the curve $\log_e u$, and as $\Delta x \to 0$, so also

* Named for Lord Napier, the inventor of logarithms. The value of e is stated below. No assumption is made at this point except that the logarithm curve has a tangent at (1, 0).

$u \to 0$; hence the secant AP becomes the tangent at A and its slope has the limit 1, by the definition of e. Hence

$$\lim_{u \to 0} \frac{\log_e(1+u)}{u} = 1.$$

Therefore $\lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \frac{1}{x} \cdot \lim_{u \to 0} \frac{\log_e(1+u)}{u} = \frac{1}{x} \cdot 1,$

or

[VIII] $$\frac{d \log_e x}{dx} = \frac{1}{x}.$$

On account of the simplicity of this formula the base e will be used henceforth in this book for all logarithms and exponentials unless the contrary is explicitly stated.

63. Differentiation of $\log_B x$. Since we have, by (4)′, § 60,

(1) $$y = \log_B x = \log_e x \cdot \log_B e,$$

the derivative of $\log_B x$ is found by multiplying the derivative of $\log_e x$ by $\log_B e$:

[VIII*a*] $$\frac{d \log_B x}{dx} = \frac{1}{x} \cdot \log_B e.$$

In particular, for common logarithms, since $B = 10$, we have

(2) $$\frac{d \log_{10} x}{dx} = \frac{1}{x} \cdot \log_{10} e.$$

The constant factor $\log_{10} e$ is the value of the slope of $y = \log_{10} x$ at (1, 0). It is called the ***modulus*** of the system of common logarithms, and is denoted by the letter M, that is $\log_{10} e = M$. Hence the preceding equation becomes

[VIIIb] $$\frac{d \log_{10} x}{dx} = \frac{M}{x}.$$

By means of formula VII, § 22, for change of variable, the formula VIII becomes

(3) $$\frac{d \log_e u}{dx} = \frac{1}{u} \cdot \frac{du}{dx}.$$

The formulas VIIIa and VIIIb may be rewritten in a similar manner.

64. Values of M and of e. To compute approximately the value of M, that is the slope of the curve $y = \log_{10} x$ at $(1, 0)$, let us draw the secant connecting the points P $(1, 0)$ and Q $(1 + \Delta x, 0 + \Delta y)$ on that curve. Let us denote the slope of this secant PQ by m_{PQ}. Then

$$m_{PQ} = \frac{\Delta y}{\Delta x} = \frac{\log_{10}(1 + \Delta x)}{\Delta x}.$$

If we choose for Δx a succession of smaller and smaller values,

$$\Delta x = 0.1,\ 0.01,\ 0.001,\ \cdots,$$

we find a corresponding succession of values of m_{PQ}:

$$m_{PQ} = 0.414,\ 0.432,\ 0.434,\ \cdots.$$

For the last of these values, a six or seven place logarithm table is required, while still higher place tables would be required to get a more accurate answer. Since the slope at $(1, 0)$ is the limit of m_{PQ} as Δx approaches zero, we have

$$M = \lim m_{PQ} = 0.434 \cdots \text{ (approximately).*}$$

From this value of M, we can compute e, since

$$\log_{10} e = M = 0.434 \cdots.$$

Hence, from a table of common logarithms,

$$e = 2.72 \cdots \text{ (approximately).}$$

65. Illustrative Examples.

Example 1. Given $y = \log_{10}(2x^2 + 3)$, to find dy/dx.

Method 1. Derivative notation. Set $u = 2x^2 + 3$, then

$$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx} = \frac{d \log_{10} u}{du} \cdot \frac{d(2x^2 + 3)}{dx} = \frac{M}{u} \cdot 4x = \frac{4Mx}{2x^2 + 3}.$$

* An independent method of calculating the values of M and of e will be given in §§ 147, 153. Logically, we might have waited until that time to state the value of M, but it is much more convenient, practically, to have an approximate value at once. To ten decimal places, the values are

$$M = 0.4342944819,\ 1/M = 2.3025850930,\ e = 2.7182818285.$$

Method 2. Differential notation.

$$dy = d\log_{10}(2x^2+3) = \frac{M}{2x^2+3}d(2x^2+3) = \frac{4Mx}{2x^2+3}dx.$$

EXAMPLE 2. Find the area under the curve $y = 1/x$ from $x = 1$ to $x = 10$, using formula [VIII] inversely:

$$A\Big]_{x=1}^{x=10} = \int_{x=1}^{x=10}\frac{1}{x}dx = \log_e x\Big]_{x=1}^{x=10} = \log_e 10 = \frac{1}{\log_{10}e} = \frac{1}{M} = 2.3026.^*$$

EXAMPLE 3. If the rate of increase dy/dx of a quantity y with respect to x is $1/x$, find y in terms of x.

Since $dy/dx = 1/x$,

$$y = \int\frac{1}{x}dx = \log_e x + c,$$

where c is a constant,—the value of y when $x = 1$. It should be noted that logarithms to the base e occur here in a perfectly natural manner; the same remark applies in Example 2. Note that

$$\log_e x = \log_{10}x \div M.$$

This case arises constantly in science. Thus, if a volume v of gas expands by an amount Δv, and if the work done in the expansion is ΔW, the ratio $\Delta W/\Delta v$ is approximately the pressure of the gas; and $dW/dv = p$ exactly. If the temperature remains constant pv = a constant; hence $dW/dv = k/v$. The general expression for W is therefore

$$W = \int\frac{k}{v}dv = k\log_e v + c,$$

and the work done in expanding from one volume v_1 to another volume v_2 is

$$W\Big]_{v=v_1}^{v=v_2} = \int_{v=v_1}^{v=v_2}\frac{k}{v}dv = k\log^e v\Big]_{v_1}^{v_2} = k\log_e\frac{v_2}{v_1} = \frac{k}{M}\log_{10}\frac{v_2}{v_1}.$$

* The number $\log_e 10 = 1 \div M = 2.302585$ is important because common logarithms (base 10) are reduced to natural logarithms (base e) by multiplying by this number, since $\log_e N = \log_{10}N \times \log_e 10$. Similarly, natural logarithms are reduced to common logarithms by multiplying by $M = \log_{10}e$; since $\log_{10}N = M\cdot\log_e N$. It is easy to remember which of these two multipliers should be used in transferring from one of these bases to the other by remembering that logarithms of numbers above 1 are surely greater when e is used as base than when 10 is used.

EXERCISES

Calculate the derivative of each of the following functions; when possible, simplify the given expression first.

1. $\log_{10} x^3$. **2.** $\log_{10} \sqrt{x}$. **3.** $\log_{10}(1 + 2x)$.

4. $\log_{10}(1 + x^3)$. **5.** $\log_e (1 + x)^3$. **6.** $\log_e \sqrt{3 + 5x}$.

7. $\log_e (1/x)$. **8.** $\log_{10} (x^{-3})$. **9.** $x \log_e x^2$.

10. $\log_e \left(\dfrac{1-x}{1+x}\right)$. **11.** $\log_{10} \left(2 - \dfrac{t}{1-t}\right)$. **12.** $\log_e \dfrac{t}{\sqrt{1-t^2}}$.

13. $\dfrac{\log_e t}{t}$. **14.** $\log_e \{\log_e x\}$. **15.** $(\log_e t)^4$.

Evaluate each of the following integrals.

16. $\displaystyle\int_1^2 \frac{5}{x} dx$. **17.** $\displaystyle\int_3^4 \frac{1-x}{x} dx$. **18.** $\displaystyle\int_5^6 \frac{2 - 3x^2 + x^4}{x^3} dx$.

19. $\displaystyle\int_{10}^{20} \frac{1+x^2}{x} dx$. **20.** $\displaystyle\int_{10}^{100} \frac{(2-t)^3}{3t^4} dt$. **21.** $\displaystyle\int_1^e \frac{6t^5 - 2t^2 - 1}{3t^3} dt$.

22. $\displaystyle\int_1^2 \frac{x^{1/2} - 1}{x^{3/2}} dx$. **23.** $\displaystyle\int_1^4 \frac{s^{3/2} - 2}{s^{5/2}} ds$. **24.** $\displaystyle\int_5^{10} (1 - u^{-1})(1 + u^{-2})\, du$.

25. Calculate the area between the hyperbola $xy = 1$ and the x-axis, from $x = 1$ to 10, 10 to 100, 100 to 1000; from $x = 1$ to $x = k$.

26. Show that the slope of the curve $y = \log_{10} x$ is a constant times the slope of the curve $y = \log_e x$. Determine this constant factor.

27. Find the flexion of the curve $y = \log_e x$, and show that there are no points of inflexion on the curve.

28. Find the maxima and minima of the curve

$$y = \log_e (x^2 - 2x + 3).$$

Find the maxima and minima and the points of inflexion (if any exist), on each of the following curves:

29. $y = x - \log_e x$. **30.** $y = x - \log_e (1 + x^2)$.

31. $y = x^2 - 4 \log_e x^2$. **32.** $y = (2x + \log x)^2$.

Find the areas under each of the following curves between $x = 2$ and $x = 5$:

33. $y = x + 1/x$. **34.** $y = (x^2 + 1)/x^3$. **35.** $y = (x^{1/2} - x)/x^2$.

36. Find the volume of the solid of revolution formed by revolving that portion of the curve $xy^2 = 1$ between $x = 1$ and $x = 3$ about the x-axis.

37. If a body moves so that its speed $v = t + 1/t$, calculate the distance passed over between the times $t = 2$ and $t = 4$.

38. Find the work done in compressing 10 cu. ft. of a gas to 5 cu. ft., if $pv = .004$.

39. Find the areas under the hyperbola $xy = k^2$ between $x = 1$ and $x = c$, c and c^2, c^2 and c^3, c^3 and c^4.

66. Differentiation of Exponential Functions. Let us consider first the function

$$(1) \qquad y = B^x.$$

Taking the logarithms of both sides of this equation with respect to the base e,

$$(2) \qquad \log_e y = x \cdot \log_e B.$$

Differentiating both sides with respect to x, we have, by VIII,

$$(3) \qquad \frac{1}{y}\frac{dy}{dx} = \log_e B, \quad \text{or} \quad \frac{dy}{dx} = y \cdot \log_e B.$$

Hence we have the formula

$$[\text{IX}a] \qquad \frac{dB^x}{dx} = B^x \cdot \log_e B.$$

For the special cases $B = e$ and $B = 10$, we have

$$[\text{IX}] \qquad \frac{de^x}{dx} = e^x,$$

$$[\text{IX}b] \qquad \frac{d10^x}{dx} = 10^x \log_e 10 = \frac{10^x}{M} = 10^x(2.302585\ldots).$$

If u denotes a function of x, we may combine any of these formulas with formula VII, § 22; thus the formula IX, which we shall use most often, becomes

$$(4) \qquad \frac{de^u}{dx} = e^u\frac{du}{dx}.$$

67. Illustrative Examples.

EXAMPLE 1. Given $y = e^{x^2}$, to find dy/dx.

Method 1. Set $x^2 = u$; then

$$\frac{dy}{dx} = \frac{dy}{du}\cdot\frac{du}{dx} = \frac{de^u}{du}\cdot\frac{d\,(x^2)}{dx} = 2\,x\cdot e^u = 2\,xe^{x^2}.$$

Method 2. $$dy = de^{x^2} = e^{x^2}\,d(x^2) = 2\,xe^{x^2}\,dx.$$

EXAMPLE 2. Find the slope of the curve

$$(1)\qquad y = \frac{e^x + e^{-x}}{2},$$

and determine its extreme values.

Since $de^{-x}/dx = -e^{-x}$, we have

$$(2)\qquad \frac{dy}{dx} = \frac{e^x - e^{-x}}{2}.$$

To determine the extreme values, first set $dy/dx = 0$:

$$\frac{e^x - e^{-x}}{2} = 0, \quad \text{or} \quad e^x = e^{-x} = \frac{1}{e^x}.$$

Clearing of fractions,

$$e^{2x} = 1, \quad \text{whence} \quad x = 0.$$

To determine whether y is really a maximum or a minimum at $x = 0$, we find

$$(3)\qquad \frac{d^2y}{dx^2} = \frac{e^x + e^{-x}}{2};$$

hence $d^2y/dx^2 = 1$ when $x = 0$. Consequently y is a minimum (§ 42, p. 66) at $x = 0$.

The curve (1) is called a ***catenary.*** This curve is very important because it is the form taken by a perfect inelastic cord hung between two points. The given function is often called the ***hyperbolic cosine*** of x, and is denoted by **cosh** x. The expression $(e^x - e^{-x})/2$ in (2) is called the ***hyperbolic sine*** of x, and is denoted by the symbol **sinh** x:

$$(4)\qquad \sinh x = \frac{e^x - e^{-x}}{2}, \qquad \cosh x = \frac{e^x + e^{-x}}{2}.$$

The equations (2) and (3) show that

$$(5)\qquad \frac{d\cosh x}{dx} = \sinh x, \qquad \frac{d\sinh x}{dx} = \cosh x.$$

EXAMPLE 3. If a quantity y has a rate of change dy/dx with respect to x proportional to y itself, to find y in terms of x. Given

$$\frac{dy}{dx} = ky,$$

we may write

$$k\frac{dx}{dy} = \frac{1}{y},$$

hence

$$kx = \int \frac{1}{y}\,dy = \log_e y + c,$$

by § 65, Ex. 3. Transposing c, we have

$$\log_e y = kx - c, \quad \text{or} \quad y = e^{kx-c} = e^{-c}e^{kx} = Ce^{kx},$$

where $C(= e^{-c})$ is again an arbitrary constant.

The only quantity y whose rate of change is proportional to itself is Ce^{kx} where C and k are arbitrary, and k is the factor of proportionality. This principle is of the greatest importance in science; a detailed discussion of concrete cases is taken up in § 68.

EXERCISES

Find the derivative of each of the following functions:

1. e^{3x}. **2.** e^{2x+x^2}. **3.** $e^{\sqrt{1+x}}$. **4.** $e^{\log x}$.

5. $x^2 e^x$. **6.** $(1-x)^3 e^{x^2}$. **7.** 10^{3x+4}. **8.** $a^{(1+x)^2}$.

9. $\log e^x$. **10.** $\log(1+e^x)$. **11.** $\log e^{-x^2}$. **12.** $(\log e^{2x})^2$.

13. $(e^x+1)^2$. **14.** $\dfrac{e^{\sqrt{x}}+e^{-\sqrt{x}}}{2}$. **15.** $\dfrac{e^{\sqrt{x}}-e^{-\sqrt{x}}}{2}$. **16.** $\dfrac{e^x-e^{-x}}{e^x+e^{-x}}$.

17. Show that the slope of the curve $y = e^x$ is equal to its ordinate.

18. Show that the area under the curve $y = e^x$ between the y-axis and any value of x is $y - 1$.

19. Find the area under the catenary from $x = 0$ to $x = 3$; from $x = -1$ to $x = +1$; from $x = 0$ to $x = a$. [See *Tables*, V, C.]

20. Find the area under the curve $y = \sinh x$ from $x = 0$ to $x = 3$; from $x = 0$ to $x = a$.

Find the maxima and minima and the points of inflexion (if any exist) on each of the following curves:

21. $y = xe^x$. **22.** $y = x^2e^x$. **23.** $y = \sinh x$.

24. $y = e^{-x^2}$. **25.** $y = xe^{-x}$. **26.** $y = \text{sech}\, x = 1 \div \cosh x$.

27. Show that the pair of parameter equations $x = \cosh t$, $y = \sinh t$ represent the rectangular hyperbola $x^2 - y^2 = 1$. Hence show that the area under the hyperbola $x^2 - y^2 = 1$ from $x = 1$ to $x = a$ is represented (see (9) § 55) by the integral

$$\int_{t=0}^{t=c} \sinh^2 t\, dt = \int_{t=0}^{t=c} [(\cosh 2t - 1)/2]\, dt,$$

where $\cosh c = a$. Hence show that this area is $(\sinh 2c)/4 - c/2$.

28. $\int_0^2 e^x\, dx.$ **31.** $\int_0^1 \sinh 2x\, dx.$ **34.** $\int_1^{10} (e^x + 1)^2\, dx.$

29. $\int_0^1 e^{-x}\, dx.$ **32.** $\int_1^2 \cosh 3x\, dx.$ **35.** $\int_{-2}^2 (e^x + 3)\, e^{-x}\, dx.$

30. $\int_1^4 e^{2x}\, dx.$ **33.** $\int_0^5 \sinh^2 x\, dx.$ **36.** $\int_{-1}^2 (e^{2x+3} + 1)\, dx.$

68. Compound Interest Law. The fact proved in the Ex. 3 of § 67 is of great importance in science:

If a variable quantity y has a rate of increase

$$\frac{dy}{dx} = ky \tag{1}$$

with respect to an independent variable x proportional to y itself, then

$$y = Ce^{kx}, \tag{2}$$

where C is an arbitrary constant.

The equation (2) between two variables x and y was called by Lord Kelvin the "*Compound Interest Law,*" on account of its crude analogy to compound interest on money. For the larger the amount y (of principal and interest) grows the faster the interest accumulates.

In science instances of a rate of growth which grows as the total grows are frequent.

Example 1. *Work in Expanding Gas.* The example used to illustrate Ex. 3, § 67, can be put in this form. Since, in the work W done in the expansion at constant temperature of a gas of volume v, we found $dW/dv = k/v$, it follows that $dv/dW = v/k$; hence $v = Ae^{W/k}$, which agrees with the result of § 67.

EXAMPLE 2. *Cooling in a Moving Fluid.* If a heated object is cooled in running water or moving air, and if θ is the varying difference in temperature between the heated object and the fluid, the rate of change of θ (per second) is assumed to be proportional to θ:

$$\frac{d\theta}{dt} = -k\theta,$$

where t is the time and where the negative sign indicates that θ is decreasing. It follows that $\theta = C \cdot e^{-kt}$. [Newton's Law of Cooling.]

Such an equation may also be thrown in the form of § 67; in this example, $dt/d\theta = -1/(k\theta)$, whence $t = -(1/k) \cdot \log_e \theta + c$, and the time taken to cool from one temperature θ_1 to another temperature θ_2 is

$$t\Big]_{\theta=\theta_1}^{\theta=\theta_2} = \int_{\theta_1}^{\theta_2} -\frac{d\theta}{k\theta} = -\frac{1}{k}\log_e \theta\Big]_{\theta_1}^{\theta_2} = -\frac{1}{k}\log_e \frac{\theta_2}{\theta_1},$$

where θ is the temperature of the body above the temperature of the surrounding fluid.

The law for the dying out of an electric current in a conductor when the power is cut off is very similar to the law for cooling in this example. See Ex. 19, p. 114.

EXAMPLE 3. *Bacterial Growth.* If bacteria grow freely in the presence of unlimited food, the increase per second in the number in a cubic inch of culture is proportional to the number present. Hence

$$\frac{dN}{dt} = kN,\ N = Ce^{kt},\ t = \frac{1}{k}\log_e N + c,$$

where N is the number of thousands per cubic inch, t is the time, and k is the rate of increase shown by a colony of one thousand per cubic inch. The time consumed in increase from one number N_1 to another number N_2 is

$$t\Big]_{N_1}^{N_2} = \int_{N_1}^{N_2} \frac{1}{k}\frac{dN}{N} = \frac{1}{k}\log_e N\Big]_{N_1}^{N_2} = \frac{1}{k}\log_e \frac{N_2}{N_1}.$$

If $N_2 = 10\,N_1$, the time consumed is $(1/k)\log_e 10 = 1/(kM)$. This fact is used to determine k, since the time consumed in increasing N tenfold can be measured (approximately). If this time is T, then $T = 1/(kM)$, whence $k = 1/(TM)$, where T is known and $M = 0.43$ (nearly).

Numerous instances similar to this occur in vegetable growth and in organic chemistry. For this reason the equation (2) on p. 110 is often called the "***law of organic growth.***" (See Exs. 20, 21, p. 114.)

EXAMPLE 4. *Atmospheric Pressure.* The air pressure near the surface of the earth is due to the weight of the air above. The pressure at the bottom of 1 cu. ft. of air exceeds that at the top by the weight of that cubic foot of air. If we assume the temperature constant, the volume of a given amount is inversely proportional to the pressure, hence the amount of air in 1 cu. ft. is directly proportional to the pressure, and therefore the weight of 1 cu. ft. is proportional to the pressure. It follows that the rate of decrease of the pressure as we leave the earth's surface is proportional to the pressure itself.

$$\frac{dp}{dh} = -kp, \; p = Ce^{-kh}, \; h = -\frac{1}{k}\log_e p + c,$$

where h is the height above the earth, and, as in Exs. 2 and 3, the difference in the height which would change the pressure from p_1 to p_2 is

$$h\Big]_{p_1}^{p_2} = -1/k \cdot \log_e\left(\frac{p_2}{p_1}\right).$$

Since $h]_{p_1}^{p_2}$, and p_2 and p_1 can be found by experiment, k is determined by the last equation.

69. Percentage Rate of Increase. The principle stated in § 68 may be restated as follows: In the case of bacterial growth, for example, while the total rate of increase is clearly proportional to the total number in thousands to the cubic inch of bacteria, *the percentage rate of increase* is constant.

In any case the ***percentage rate of increase***, r_p, is obtained by dividing 100 times the *total rate of increase by the total amount of the quantity*, $100 \cdot (dy/dx) \div y$; and since the equation $dy/dx = ky$ gives $(dy/dx) \div y = k$, it is clear that the *percentage rate of increase in any of these problems is a constant.* The quotient $(dy/dx) \div y$, that is, 1/100 of the percentage rate of increase, will be called the ***relative rate of increase***, and will be denoted by r_r.

In some of the exercises which follow, the statements are phrased in terms of *percentage* rate of increase, r_p, or the *relative* rate of increase, $r_r = r_p \div 100$.

EXERCISES

Find dy/dx and $(dy/dx) \div y$ for each of the following functions:

1. $7\,e^{3x}$.
2. $4\,e^{-2.5x}$.
3. xe^x.
4. e^{x^2}.
5. e^{4x+5}.
6. $(x^2+2)e^x$.
7. $(ax+b)e^{kx}$.
8. $(x^2+px+q)e^x$.
9. $(3\,x+2)e^{-x^2}$.

10. If a body cools in moving air, according to Newton's law, $d\theta/dt = -k\theta$, where t is the time (in seconds) and θ is the difference in temperature between the body and the air, find k if θ falls from 40° C. to 30° C. in 200 seconds.

11. How soon will the difference in temperature θ in Ex. 10 fall to 10° C.?

12. In measuring atmospheric pressure, it is usual to express the pressure in millimeters (or in inches) of mercury in a barometer. Find C in the formula of Ex. 4, § 68, if $p = 762$ mm. when $h = 0$ (sea level). Find C if $p = 30$ in. when $h = 0$.

13. Using the value of C found in Ex. 12, find k in the formula for atmospheric pressure if $p = 24$ in. when $h = 5830$ ft.; if $p = 600$ mm. when $h = 1909$ m. Hence find the barometric reading at a height of 3000 ft.; 1000 m. Find the height if the barometer reads 28 in.; 650 mm.

[NOTE. Pressure in pounds per square inch = 0.4908 × barometer reading in inches.]

14. If a rotating wheel is stopped by water friction, the rate of decrease of angular speed, $d\omega/dt$, is proportional to the speed. Find ω in terms of the time, and find the factor of proportionality if the speed of the wheel diminishes 50% in one minute.

15. If a wheel stopped by water friction has its speed reduced at a constant rate of 2% (in revolutions per second and seconds), how long will it take to lose 50% of the speed?

16. The length l of a rod when heated expands at a constant rate per cent ($= 100\,k$). Show that $dl/d\theta = kl$, where θ is the temperature; if the percentage rate of increase is .001% (in feet and degrees C.), how much longer will it be when heated 200° C.? At what temperature will the rod be 1% longer than it was originally?

[NOTE. This value of k is about correct for cast iron.]

17. The ***coefficient of expansion*** of a metal rod is the increase in length per degree rise in temperature of a rod of unit length. Show that the coefficient of expansion of any rod is the relative rate of increase in length with respect to the temperature.

18. When a belt passes around a pulley, if T is the tension (in pounds) at a distance s (in feet) from the point where the belt leaves the pulley, r the radius of the pulley, and μ the coefficient of friction, then $dt/ds = \mu T/r$. Express T in terms of s. If $T = 30$ lb. when $s = 0$, what is T when $s = 5$ ft., if $r = 7$ ft., and $\mu = 0.3$?

19. When an electric circuit is cut off, the rate of decrease of the current is proportional to the current C. Show that $C = C_0e^{-kt}$, where C_0 is the value of C when $t = 0$.

[NOTE. The assumption made is that the electric pressure, or electromotive force, suddenly becomes zero, the circuit remaining unbroken. This is approximately realized in one portion of a circuit which is short-circuited. The effect is due to ***self-induction:*** $k = R/L$, where R is the resistance and L the self-induction of the circuit.]

20. Radium automatically decomposes at a constant (relative) rate. Show that the quantity remaining after a time t is $q = q_0e^{-kt}$, where q_0 is the original quantity. Find k from the fact that half the original quantity disappears in 1800 yrs. How much disappears in 100 yrs.? in one year?

21. Many other chemical reactions — for example, the formation of invert sugar from sugar — proceed approximately in a manner similar to that described in Ex. 20. Show that the quantity which remains is $q = q_0e^{-kt}$ and that the amount transformed is $A = q_0 - q = q_0(1 - e^{-kt})$. Show that the quantities which remain after a series of equal intervals of time are in geometric progression.

22. The amount of light which passes through a given thickness of glass, or other absorbing material, is found from the fact that a fixed per cent of the total is absorbed by any absorbing material. Express the amount which will pass through a given thickness of glass.

70. Logarithmic Differentiation. Relative Increase. In § 69 we defined the *relative rate of increase* r_r of a quantity y with respect to x as the total rate of increase (dy/dx) divided by y. If y is given as a function of x,

$$(1) \qquad y = f(x),$$

the relative rate of increase

$$r_r = \frac{dy}{dx} \div y$$

can be obtained by taking the logarithms of both sides of (1),*

$$\log_e y = \log_e f(x), \tag{2}$$

and then differentiating both sides with respect to x:

$$r_r = \frac{1}{y} \cdot \frac{dy}{dx} = \frac{d \log_e y}{dx} = \frac{d \log_e f(x)}{dx}. \tag{3}$$

This process is often called ***logarithmic differentiation: the logarithmic derivative of a function is its relative rate of increase, r_r,*** or 1/100 of its percentage rate of increase.

EXAMPLE 1. Given $y = Ce^{kx}$, to find $r_r = (dy/dx) \div y$. Taking logarithms on both sides:

$$\log_e y = \log_e C + kx;$$

differentiating both sides with respect to x,

$$r_r = \frac{dy}{dx} \div y = \frac{d \log_e y}{dx} = k.$$

The result of Ex. 3, § 68, may be restated as follows: the only function of x whose relative rate of change (logarithmic derivative) is constant is Ce^{kx}.

EXAMPLE 2. Given $y = x^2 + 3x + 2$, to find r_r.

Method 1. $\dfrac{dy}{dx} = 2x + 3$, hence $r_r = \dfrac{dy}{dx} \div y = \dfrac{2x + 3}{x^2 + 3x + 2}$.

Method 2. $r_r = \dfrac{dy}{dx} \div y = \dfrac{d \log y\dagger}{dx} = \dfrac{d \log (x^2 + 3x + 2)}{dx} = \dfrac{2x + 3}{x^2 + 3x + 2}$.

* Since log N is defined only for positive values of N, *all that follows holds only for positive values of the quantities whose logarithms are used.*

† Here and hereafter the symbol log will be used to mean a logarithm to the base e.

71. Logarithmic Methods. The process of logarithmic differentiation is often used apart from its meaning as a relative rate, simply as a device for obtaining the usual derivative. We shall first apply this method to prove the rule for differentiating any *constant* power of a variable. The equation

$$y = x^n$$

gives

$$\log y = n \log x.$$

Differentiating with respect to x, we have

$$\frac{1}{y}\frac{dy}{dx} = n \cdot \frac{1}{x}$$

or

$$\frac{dy}{dx} = n \cdot \frac{y}{x} = n \cdot \frac{x^n}{x}$$

$$= nx^{n-1}.$$

In this proof, n may be any constant whatever. (See §§ 17, 21.)

The logarithmic method is useful also in such examples as those that follow.

Example 1. Given $y = (2x^2 + 3)10^{4x-1}$.

Method 1. Ordinary Differentiation.

$$\frac{dy}{dx} = (2x^2+3)\frac{d}{dx}(10^{4x-1}) + 10^{4x-1}\frac{d}{dx}(2x^2+3)$$

$$= (2x^2+3) \cdot 4 \cdot \frac{1}{M} 10^{4x-1} + 10^{4x-1} \cdot 4x$$

$$= 4 \cdot 10^{4x-1}\Big[(2x^2+3)/M + x\Big], \text{ where } M = \log_{10} e = 0.434.$$

Method 2. Logarithmic Method.

Since $\log y = \log(2x^2+3) + (4x-1)\log 10$, we have

$$\frac{1}{y} \cdot \frac{dy}{dx} = \frac{4x}{2x^2+3} + 4 \cdot \log 10,$$

or $$\frac{dy}{dx} = y\left[\frac{4x}{2x^2+3} + 4\log 10\right] = 4\cdot 10^{4x-1}\,[x + (2x^2+3)\log 10],$$

which agrees with the preceding result, since $\log_e 10 = 1/\log_{10} e = 1/M$.

EXAMPLE 2. Given $y = (3x^2+1)^{2x+4}$, to find dy/dx. Since no rule has been given for a variable to a variable power, ordinary differentiation cannot be used advantageously. Taking logarithms, however, we find

$$\log y = (2x+4)\log(3x^2+1),$$

whence $$\frac{1}{y}\cdot\frac{dy}{dx} = 2\log(3x^2+1) + \frac{6x}{3x^2+1}(2x+4),$$

or $$\frac{dy}{dx} = (3x^2+1)^{2x+4}\left\{2\log(3x^2+1) + \frac{6x}{3x^2+1}(2x+4)\right\}.$$

The use of the logarithmic method is the only expeditious way to find the derivative in this example.

EXERCISES

Find the logarithmic derivatives (relative rates of increase) of each of the following functions, by each of the two methods of § 71.

1. e^{-2x}. **5.** $0.1\,e^{10t-5}$. **9.** $(r^2+1)\,e^{-r^2}$.

2. $4\,e^{4t}$. **6.** 10^{2x+3}. **10.** $(2-3t^2)\,e^{2t^3-1}$.

3. e^{3t+2}. **7.** $e^{-x^2+kx^3}$. **11.** $(1-t^2+t^4)\,10^{t^3+3t}$.

4. e^{-x^2}. **8.** $2\,t^2e^{-7t}$. **12.** e^{e^r}.

Find the derivative of each of the following functions by the logarithmic method.

13. $(1+x)^{1+x}$. **15.** $x^{\sqrt{x}}$. **17.** $(1+x)(1+2x)(1+3x)$.

14. $(s^2+1)^{2s+3}$. **16.** t^{e^t}. **18.** $\sqrt[3]{1+s^2} \div \sqrt{1-s^2}$.

19. If $y = uv$, show that $dy \div y = du \div u + dv \div v$. In general show that the relative rate of increase of a *product* is the *sum* of the relative rates of increase of the factors.

20. If a rectangular sheet of metal is heated, show that the relative rate of increase in its area is twice the coefficient of expansion of the material [see Ex. 17, List XXXI].

21. Extend the rule of Ex. 19 to the case of any number of factors. Apply this to the expansion of a heated block of metal.

22. Show directly, and also by use of Ex. 21, that the relative rate of increase of x^n with respect to x, where n is an integer, is n/x.

23. Compare the functions e^{2x} and e^{2x+3}; compare their relative rates of increase; compare their derivatives; compare their second derivatives.

Compare the following pairs of functions, their logarithmic derivatives, their ordinary derivatives, and their second derivatives.

24. e^x and 10^x.

25. e^{ax} and e^{ax+b}.

26. e^{ax} and 10^{bx}.

27. e^{-ax} and e^{+ax}.

28. e^{-x^2} and sech x.

29. e^{-x^2} and $1 \div (a + bx^2)$.

30. Can k be found so that ke^{ax} and 10^{bx} coincide? Prove this by comparing their logarithmic derivatives, and find b in terms of a.

31. If the logarithmic derivative $(dy/dx) \div y$ is equal to $3 + 4x$, show that $\log y = 3x + 2x^2 +$ const., or $y = ke^{3x+2x^2}$.

32. If $(dy/dx) \div y = f(x)$ show that $y = ke^{\int f(x)\,dx}$.

Find y if the logarithmic derivative has any one of the following values:

33. $1 - x$.

34. $ax + bx^2$.

35. n/x.

36. $a + n/x$.

37. e^x.

38. $e^x + n/x$.

CHAPTER IX

TRIGONOMETRIC FUNCTIONS

72. Limit of $(\sin \theta)/\theta$ as θ approaches Zero. To find the derivatives of $\sin x$ and $\cos x$, we shall make use of the limit

$$\lim_{\theta \to 0} \frac{\sin \theta}{\theta}.$$

Let θ be the angle AOB, Fig. 27, and let us draw a circle about O as center with a radius $r = OA$, cutting OB at P. Draw PP' and BB' perpendicular to OA and draw $OP'B'$. Then

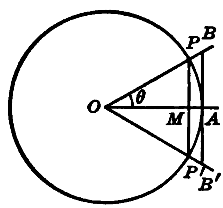

FIG. 27.

$$(1) \qquad PP' < \text{arc}\, PAP' < BB',$$

or

$$(2) \qquad 2\,r \sin \theta < 2\,r \cdot \theta < 2\,r \tan \theta,$$

since arc $PAP' = 2\,r \cdot \theta$ if θ is measured in circular measure. Dividing by $2\,r \sin \theta$, we have

$$(3) \qquad 1 < \frac{\theta}{\sin \theta} < \frac{1}{\cos \theta}.$$

But $\cos \theta$ approaches 1 as θ approaches zero. Hence $\theta/\sin \theta$ must also approach 1. It follows that

$$(4) \qquad \lim_{\theta \to 0} \frac{\sin \theta}{\theta} = 1,$$

provided, as above, that θ is measured in circular measure.*

* On account of the simplicity of this formula and those that result from it, we shall assume henceforth that *all angles are measured in circular measure.*

73. Derivatives of $\sin x$ and $\cos x$. Given the equation

$$y = \sin x, \tag{1}$$

we proceed to find dy/dx by the fundamental process of § 17. We have, using the notation of § 17,

$$y + \Delta y = \sin (x + \Delta x) \tag{A}$$

$$\begin{aligned} \Delta y &= \sin (x + \Delta x) - \sin x \\ &= 2 \cos \left(x + \frac{\Delta x}{2}\right) \sin \frac{\Delta x}{2}, \end{aligned} \tag{B}$$

by formula 13, Tables, II, G. Dividing both sides by Δx,

$$\frac{\Delta y}{\Delta x} = \cos \left(x + \frac{\Delta x}{2}\right) \frac{\sin \frac{\Delta x}{2}}{\frac{\Delta x}{2}}, \tag{C}$$

or, if we put $\theta = \dfrac{\Delta x}{2}$,

$$\frac{\Delta y}{\Delta x} = \cos (x + \theta) \frac{\sin \theta}{\theta}.$$

Hence, by § 72,

$$\frac{dy}{dx} = \lim_{\theta \to 0} \frac{\Delta y}{\Delta x} = \cos x, \tag{D}$$

and we have the formula

$$\frac{d \sin x}{dx} = \cos x. \tag{X}$$

Similarly, starting with $y = \cos x$, we obtain the formula

$$\frac{d \cos x}{dx} = - \sin x. \tag{XI}$$

By means of formula VII, § 22, these formulas may be rewritten in the form

$$\frac{d \sin u}{dx} = \frac{d \sin u}{du} \cdot \frac{du}{dx} = \cos u \frac{du}{dx}, \tag{2}$$

$$\frac{d \cos u}{dx} = \frac{d \cos u}{du} \cdot \frac{du}{dx} = - \sin u \frac{du}{dx}. \tag{3}$$

EXAMPLE 1. Differentiate $y = \sin \sqrt{1 + x^2}$.

$$\frac{dy}{dx} = \frac{d \sin \sqrt{1+x^2}}{dx} = \cos \sqrt{1+x^2}\, \frac{d\sqrt{1+x^2}}{dx} = \frac{x}{\sqrt{1+x^2}} \cos \sqrt{1+x^2}.$$

EXAMPLE 2. Differentiate $y = \cos e^{x^2}$.

$$\frac{dy}{dx} = \frac{d \cos e^{x^2}}{dx} = -\sin e^{x^2} \frac{de^{x^2}}{dx} = -2xe^{x^2} \sin e^{x^2}.$$

74. Derivatives of tan x, ctn x, sec x, csc x. Given $y = \tan x$, we may write

$$\frac{dy}{dx} = \frac{d \tan x}{dx} = \frac{d\dfrac{\sin x}{\cos x}}{dx} = \frac{\cos x \dfrac{d \sin x}{dx} - \sin x \dfrac{d \cos x}{dx}}{\cos^2 x} = \frac{1}{\cos^2 x}.$$

[XII] $$\frac{d \tan x}{dx} = \frac{1}{\cos^2 x} = \sec^2 x.$$

Similarly,

[XIII] $$\frac{d \operatorname{ctn} x}{dx} = \frac{d\dfrac{\cos x}{\sin x}}{dx} = -\frac{1}{\sin^2 x} = -\csc^2 x.$$

[XIV] $$\frac{d \sec x}{dx} = \frac{d\dfrac{1}{\cos x}}{dx} = \frac{\sin x}{\cos^2 x} = \sec x \tan x.$$

[XV] $$\frac{d \csc x}{dx} = \frac{d\dfrac{1}{\sin x}}{dx} = \frac{-\cos x}{\sin^2 x} = -\csc x \operatorname{ctn} x.$$

These may be combined with formula VII, § 22, as in § 73.

EXAMPLE 1. Differentiate $y = \cos^3 x$.

Setting $u = \cos x$, we have $y = u^3$, and

$$\frac{dy}{dx} = \frac{du^3}{dx} = 3u^2 \frac{du}{dx} = 3 \cos^2 x \frac{d \cos x}{dx} = -3 \cos^2 x \sin x.$$

EXAMPLE 2. Differentiate $y = \cos^3 (2x^2 + 1)$.

Setting $u = \cos (2x^2 + 1)$, we have $y = u^3$, and

$$\frac{dy}{dx} = \frac{du^3}{dx} = 3u^2 \frac{du}{dx} = 3 \cos^2 (2x^2 + 1) \cdot \frac{du}{dx}.$$

But

$$\frac{du}{dx} = \frac{d \cos (2\,x^2 + 1)}{dx} = -\sin (2\,x^2 + 1) \cdot \frac{d\,(2\,x^2 + 1)}{dx}$$
$$= -4\,x \sin(2\,x^2 + 1).$$

Hence

$$\frac{dy}{dx} = [3 \cos^2 (2\,x^2 + 1)]\,[-4\,x \sin (2\,x^2 + 1)]$$
$$= -12\,x \cos^2 (2\,x^2 + 1) \sin (2\,x^2 + 1).$$

EXERCISES

Find the derivatives of:

1. $\sin 4\,x$. **5.** $\sin x^4$. **9.** $x \cos x$.

2. $\cos (\theta/3)$. **6.** $\tan (3 - 2\,t)$. **10.** $e^\theta \operatorname{ctn} \theta$.

3. $\tan (-2\,\theta)$. **7.** $\cos (-3\,\theta)$. **11.** $\log \sec x$.

4. $\sin^2 x$. **8.** $\sec (x/2)$. **12.** $\cos e^{-x}$.

13. $\sin x - 4 \cos 2\,x$. **17.** $e^t \cos^2 (3\,t - 1)$.

14. $e^t \sin (\pi/10 - 2\,t)$. **18.** $e^{1+2t} \sin (3\,t - \pi/4)$.

15. $(1 + x^2) \sin (3 - 2\,x)$. **19.** $e^{t/10} (\cos t - 4 \sin 3\,t)$.

16. $\log \sec e^{\sin x}$. **20.** $\cos \log \tan e^x$.

21. Find the area under the curve $y = \sin x$ from $x = 0$ to $x = \pi/2$; test the correctness of your result by rough comparison with the circumscribed rectangle.

22. Find the area bounded by the two axes and the curve $y = \cos x$, in the first quadrant.

Find the maxima and minima, and the points of inflexion (if any exist) on each of the following curves.

23. $y = \sin x$. **26.** $y = x \cos x$. **29.** $y = e^{-x} \sin x$.

24. $y = \cos x$. **27.** $y = 1 - \sin 2\,x$. **30.** $y = e^{-2x} \sin x$.

25. $y = \tan x$. **28.** $y = \sin x + \cos x$. **31.** $y = \cos (2\,x + \pi/6)$.

Find the derivative of each of the following pairs of functions, and draw conclusions concerning the functions.

32. $\cos x$ and $\sin (\pi/2 - x)$. **35.** $\sin 2\,x$ and $2 \sin x \cos x$.

33. $\cos^2 x$ and $1 - \sin^2 x$. **36.** $\cos 2\,x$ and $-2 \sin^2 x$.

34. $\sec x$ and $\sec (-x)$. **37.** $\tan^2 x$ and $\sec^2 x$.

Integrate the following expressions; in case the limits are stated, evaluate the integrals, and represent them graphically as areas.

38. $\int_0^{\pi/3} \sin x\, dx.$ **40.** $\int_0^{\pi/4} \sec^2 x\, dx.$ **42.** $\int \cos (3t + \pi/6)\, dt.$

39. $\int_{\pi/2}^{+\pi/2} \cos x\, dx.$ **41.** $\int \sin 2x\, dx.$ **43.** $\int \tan t \sec t\, dt.$

44. $\int_0^{\pi} (1 + \sin x)\, dx.$

45. $\int (\cos x + 3 \sin 2x)\, dx.$

46. $\int \cos^2 x\, dx.$

HINT. $2 \cos^2 x = 1 + \cos 2x.$

47. $\int (\cos 2x - 1)\, dx.$ **48.** $\int_0^{\pi/2} \sin^2 x\, dx.$

49. Find the derivative of $\sin x$ by showing that

$$\sin (x + \Delta x) - \sin x = \sin x (\cos \Delta x - 1) + \cos x \cdot \sin \Delta x$$

and remarking that, as $\Delta x \to 0$,

$$\lim [(\cos \Delta x - 1) \div \Delta x] = 0 \text{ and } \lim [(\sin \Delta x) \div \Delta x] = 1.$$

50. Find the derivative of $\cos x$ as in Ex. 49.

51. Find the derivatives of the two functions

(*a*) $\text{vers } x = 1 - \cos x.$ (*b*) $\text{exsec } x = \sec x - 1.$

52. Differentiate some of the *answers* in the list of formulas, *Tables*, IV, E_a, E_b. What should the result of your differentiation be?

[The teacher will indicate which formulas should be thus tested.]

Find the speed of a moving particle whose motion is given in terms of the time t by one of the pairs of parameter equations which follow; and find the path in each case.

53. $\begin{cases} x = 3 \cos 2t. \\ y = 3 \sin 2t. \end{cases}$ **55.** $\begin{cases} x = \sin t + \cos t. \\ y = \sin t. \end{cases}$

54. $\begin{cases} x = 2 \cos 4t. \\ y = 3 \sin 4t. \end{cases}$ **56.** $\begin{cases} x = \sec t. \\ y = \tan t. \end{cases}$

57. A flywheel 5 ft. in diameter makes 1 revolution per second. Find the horizontal and the vertical speed of a point on its rim 1 ft. above the center.

58. A point on the rim of a flywheel of radius 5 ft. which is 3 ft. above the center has a horizontal speed of 20 ft. per second. Find the angular speed, and the total linear speed of a point on the rim.

75. Simple Harmonic Motion. If a point M moves with constant speed in a circular path, the projection P of that point on any straight line is said to be in simple harmonic motion.

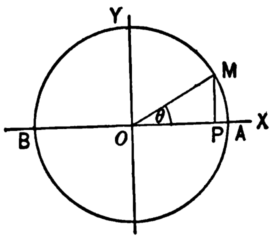

FIG. 28.

Let the circle have a radius a; let the constant speed be v; and let the straight line be taken as the x-axis. We may suppose the center of the circle lies on the straight line, since the projection of the moving point on either of two parallel straight lines has the same motion. Let the center O of the circle be the origin. Then we have

$$(1) \qquad x = OP = a\cos\theta, \text{ or } x = a\cos(s/a),$$

where $s = \text{arc } AM$, since $\theta = s/a$. Moreover, since the speed v is constant, $v = s/T$, if T is the time since M was at A; or $v = s/(t - t_0)$ if t is measured from any instant whatever, and t_0 is the value of t when M is at A. We have therefore

$$(2) \qquad x = a\cos\frac{s}{a} = a\cos\left[\frac{v}{a}(t - t_0)\right] = a\cos[kt + \epsilon];$$

where $k = v/a$, and $\epsilon = -kt_0 = -vt_0/a$.

From (2), the speed dx/dt of P along BA is

$$(3) \qquad v_x = \frac{dx}{dt} = \frac{d[a\cos(kt + \epsilon)]}{dt} = -ak\sin(kt + \epsilon),$$

and the acceleration of P is

$$(4) \qquad j_T = \frac{d^2x}{dt^2} = -ak^2\cos(kt + \epsilon) = -k^2\cdot x,$$

or,

$$(5) \qquad j_T \div x = \frac{d^2x}{dt^2} \div x = -k^2;$$

that is, the acceleration of x divided by x, is a negative constant, $-k^2$. We shall see that much of the importance of simple harmonic motion arises from this fact.

It is important to notice that (2) may be written in the form

$$x = a\cos(kt + \epsilon) = a[\cos\epsilon\cos kt - \sin\epsilon\sin kt],$$

or

$$\mathbf{x = A\sin kt + B\cos kt,} \tag{6}$$

where $A = -a\sin\epsilon$ and $B = +a\cos\epsilon$ are both constants. The form (6) may be used to derive (5) directly.

The simplest forms of the equation (6) result when $k = 1$ and either $A = 0$ and $B = 1$, or $A = 1$ and $B = 0$:

$$(7)\ \begin{cases} x = \sin t;\ \text{if } k = 1, A = 1, B = 0, \textit{i.e. } a = 1,\ \epsilon = 3\,\pi/2. \\ x = \cos t;\ \text{if } k = 1, A = 0, \mathrm{B} = 1, \textit{i.e. } a = 1,\ \epsilon = 0. \end{cases}$$

The formulas (2) and (6) are general formulas for simple harmonic motion; (7) represent two specially simple cases.

76. Vibration. The importance of simple harmonic motion, based on its property (5) of § 75, is evident in *vibrating bodies*, such as vibrating cords or wires, the prongs of a tuning fork, the atoms of water in a wave, a weight suspended by a spring.

In all such cases, it is natural to suppose that the force which tends to restore the vibrating particle to its central position increases with the distance from that central position, and is proportional to that distance. (Compare Hooke's law in Physics.)

It is a standard law of physics, equivalent to Newton's second law of motion, that the acceleration of any particle is proportional to the force acting upon it.

In the case of vibration, therefore, the acceleration, being proportional to the force, is proportional to the distance, x, from the central position; it follows that, in ordinary vibrations, the relative acceleration is a negative constant, — negative, because the acceleration is opposite to the positive direction of motion. For this reason, each particle of a vibrating body is supposed to have a simple harmonic motion, unless disturbing causes, such as air friction, enter to change the result. Neglecting such frictional effects temporarily, the distance x from the central position is, as in § 75,

$$x = a \cos (kt + \epsilon) = A \sin kt + B \cos kt,$$

where t denotes the time measured from a starting time t_0 seconds before the particle is at $x = a$, and where $\epsilon = -t_0k$. Moreover, from § 75 and also from what precedes,

$$\frac{dx^2}{dt^2} = -k^2x.$$

The quantity a is called the *amplitude*, $2\pi/k$ is called the *period*, and $t_0 = -\epsilon/k$ is called the *phase*, of the vibration.

EXERCISES

Find the speed and the acceleration of a particle whose displacement x has one of the following values: compare the acceleration with the original expression for the displacement.

1. $x = \sin 2t$.
2. $x = \sin (t/2 - \pi/4)$.
3. $x = \sin t - \frac{1}{2} \sin 2t$.
4. $x = \cos t + \frac{1}{3} \cos 3t$.
5. $x = \sin 2t + 0.15 \sin 6t$.
6. $x = \sin t - \frac{1}{3} \sin 3t + \frac{1}{5} \sin 5t$.
7. $x = a \sin (kt + e)$.
8. $x = A \cos kt + B \sin kt$.

9. Determine the angular acceleration of a hair spring if it vibrates according to the law $\theta = .2 \sin 10\,\pi t$; what is the amplitude of one vibration, the period and the extreme value of the acceleration?

Show that each of the following functions satisfies an equation of the form $d^2u/dt^2 + k^2u = 0$ or $d^2u/dt^2 - k^2u = 0$; in each case determine the value of k.

10. $u = 10 \sin 2t$.

11. $u = 0.7 \cos 15t$.

12. $u = 3e^{4t}$.

13. $u = 20e^{-4t}$.

14. $u = \sin (3t + \pi/3)$.

15. $u = 5 \cos (t/3 - \pi/12)$.

16. $u = 12 \cos 3t - 5 \sin 3t$.

17. $u = 3 \sin 6t + 4 \cos 6t$.

18. $u = C_1 \sin 3t + C_2 \cos 3t$.

19. $u = C_1e^{7t} + C_2e^{-7t}$.

20. Show that the function $u = A \sin kt + B \cos kt$ always satisfies the equation $d^2u/dt^2 + k^2u = 0$ for any values of A and B. Check by substituting various positive and negative values for k, A, B.

21. Show that $u = Ae^{kt} + Be^{-kt}$ always satisfies the equation

$$\frac{d^2u}{dt^2} - k^2u = 0.$$

22. When an electrical condenser discharges through a negligible resistance the current C follows the law $d^2C/dt^2 = -a^2C$, where a is a constant. Express the current in terms of the time. When $a = 1000$, what is the frequency (number of alternations) per second?

23. Any ordinary alternating electric current varies in intensity according to the law $C = a \sin kt$; find the maximum current and the time-rate of change of the current.

24. When a pendulum of length l swings through a small angle θ, its motion is represented by the equation $d^2\theta/dt^2 = -g\theta/l$, very nearly, l being in feet, θ in radians, t in seconds. Show that

$$\theta = C_1 \sin kt + C_2 \cos kt,$$

where $k = \sqrt{g/l}$. Find C_1 and C_2 if $\theta = \alpha$ and the angular speed $\omega = 0$ when $t = 0$; and find the time required for one full swing.

25. A needle is suspended in a horizontal position by a torsion filament. When the needle is turned through a small angle from its position of equilibrium, the torsional restoring force produces an angular acceleration nearly proportional to the angular displacement. Neglecting resistances, what will be the nature of the motion?

77. Inverse Trigonometric Functions. The equation

(1) $$y = \sin^{-1} x.$$

is equivalent to the equation

(2) $$\sin y = x.$$

Differentiating each side with respect to x, we find

(3) $$\cos y \frac{dy}{dx} = 1, \text{ or } \frac{dy}{dx} = \frac{1}{\cos y} = \frac{1}{\sqrt{1 - x^2}}.$$

Hence we have the formula

[XVI] $$\frac{d \sin^{-1} x}{dx} = \frac{1}{\sqrt{1 - x^2}}.$$

It is evident that the radical in these expressions should have the same sign as $\cos y$, *i.e. plus* when y is in the first or in the fourth quadrant, *minus* when y is in the second or in the third quadrant.

Combining XVI with VII, § 22, we may write

(4) $$\frac{d \sin^{-1} u}{dx} = \frac{1}{\sqrt{1 - u^2}} \frac{du}{dx}.$$

In a similar manner, we find from formulas XI, XII, XIII, XIV, XV, the formulas

[XVII] $$\frac{d \cos^{-1} x}{dx} = \frac{-1}{\sqrt{1 - x^2}}$$

(radical + in 1st and 2d quadrants).

[XVIII] $$\frac{d \tan^{-1} x}{dx} = \frac{1}{1 + x^2} \text{ (all quadrants).}$$

[XIX] $$\frac{d \operatorname{ctn}^{-1} x}{dx} = \frac{-1}{1 + x^2} \text{ (all quadrants).}$$

[XX] $$\frac{d \sec^{-1} x}{dx} = \frac{1}{x\sqrt{x^2 - 1}}$$

(radical + in 1st and 3d quadrants).

[XXI] $$\frac{d \csc^{-1} x}{dx} = \frac{-1}{x\sqrt{x^2-1}}$$

(radical + in 1st and 3d quadrants).

[XXII] $$\frac{d \operatorname{vers}^{-1} x}{dx} = \frac{1}{\sqrt{2x-x^2}}$$

(radical + in 1st or 2d quadrants).

Each of these formulas may be combined with VII, § 22, as in equation (4) above.

78. Illustrative Examples.

EXAMPLE 1. $$\frac{d \sin^{-1} x^2}{dx} = \frac{1}{\sqrt{1-(x^2)^2}} \frac{d(x^2)}{dx} = \frac{2x}{\sqrt{1-x^4}}.$$

EXAMPLE 2. $$\frac{d \tan^{-1} e^x}{dx} = \frac{1}{1+(e^x)^2} \frac{de^x}{dx} = \frac{e^x}{1+e^{2x}}.$$

EXAMPLE 3. $$\frac{d (\sec^{-1} x)^3}{dx} = 3 (\sec^{-1} x)^2 \frac{d \sec^{-1} x}{dx}.$$

$$= 3 (\sec^{-1} x)^2 \frac{1}{x\sqrt{x^2-1}}.$$

EXAMPLE 4. $$\frac{d \log (\cos^{-1} x)}{dx} = \frac{1}{\cos^{-1} x} \frac{d \cos^{-1} x}{dx}.$$

$$= \frac{1}{\cos^{-1} x} \frac{-1}{\sqrt{1-x^2}}.$$

79. Integrals of Irrational Functions. By reversal of the formulas for the derivatives of the inverse trigonometric functions, XVI–XXII, we obtain the integrals of certain important irrational functions.

[XVI]$_i$ $$\int \frac{dx}{\sqrt{1-x^2}} = \sin^{-1} x + C, \text{ since } \frac{d \sin^{-1} x}{dx} = \frac{1}{\sqrt{1-x^2}},$$

[XVII]$_i$ $$\int \frac{dx}{1+x^2} = \tan^{-1} x + C, \text{ since } \frac{d \tan^{-1} x}{dx} = \frac{1}{1+x^2},$$

$$[\text{XX}]_i \quad \int \frac{dx}{x\sqrt{x^2-1}} = \sec^{-1} x + C, \text{ since } \frac{d \sec^{-1} x}{dx} = \frac{1}{x\sqrt{x^2-1}},$$

$$[\text{XXII}]_i \quad \int \frac{dx}{\sqrt{2x-x^2}} = \text{vers}^{-1} x + C, \text{ since } \frac{d\, \text{vers}^{-1} x}{dx} = \frac{1}{\sqrt{2x-x^2}},$$

where C in each case denotes an arbitrary constant. Since $\sin^{-1} x + \cos^{-1} x = \pi/2$, the student may show that [XVII] leads to the same result as [XVI].

EXAMPLE. To find the area under the curve $y = 1/(1 + x^2)$ from the point where $x = 0$ to the point where $x = 1$.

Since $A = \int y\, dx$, we have

$$A\Big]_{x=0}^{x=1} = \int_{x=0}^{x=1} \frac{1}{1+x^2}\, dx = \tan^{-1} x\Big]_{x=0}^{x=1} = \pi/4 - 0 = \pi/4.$$

The fact that we are using radian measure for angles appears very prominently here. Draw the curve (by first drawing $y = 1 + x^2$) on a large scale on millimeter paper and actually count the small squares as a check on this result.

EXERCISES

Differentiate each of the following functions.

1. $\sin^{-1} x^4$.
2. $\cos^{-1} (1 - x)$.
3. $\sin^{-1} (1/x)$.
4. $\tan^{-1} (3\, x)$.
5. $\sin^{-1} \sqrt{1 - x^2}$.
6. $x \sin^{-1} x$.
7. $\tan^{-1} (1/x^2)$.
8. $e^x \cos^{-1} x$.
9. $\log \tan^{-1} x$.
10. $\cos^{-1} (xe^x)$.
11. $x^2 \tan^{-1} 2\sqrt{x}$.
12. $\sec^{-1}(x^2 + 1)$.
13. $\csc^{-1} \sqrt{1 + x^2}$.
14. $\text{ctn}^{-1} \left(\frac{1 + e^x}{1 - e^x}\right)$.
15. $\cos^{-1} (e^{\sin x})$.
16. $\tan^{-1} (\log e^x)$.
17. $\cos^{-1} \sqrt{1 - x^2}$.
18. $\sec^{-1} (\log \tan x)$.
19. $e^{\sin^{-1} x}$.
20. $10^{\tan^{-1} x}$.
21. $(\log \tan^{-1} x)^3$.
22. $\frac{1}{\tan^{-1} x}$.
23. $\frac{\sin^{-1} \sqrt{x}}{1 - x}$.

Integrate the following functions; in case limits are stated, evaluate the integral.

24. $\int_0^{\sqrt{3}} \frac{dx}{1+x^2}$.

25. $\int_{1/2}^{1} \frac{dt}{\sqrt{1-t^2}}$.

26. $\int_{-1}^{+1} \frac{dx}{1+x^2}$.

27. $\int_1^2 \frac{d\theta}{\theta\sqrt{\theta^2-1}}$.

28. $\int \frac{dx}{1+4x^2}$. [Set $u = 2x$.]

29. $\int \frac{dx}{\sqrt{1-4x^2}}$. [Set $u = 2x$.]

Integrate after making the change of letters $u = 1 - x$.

30. $\int \frac{dx}{\sqrt{1-(1-x)^2}}$. **31.** $\int \frac{dx}{1+(1-x)^2}$. **32.** $\int \frac{dx}{\sqrt{2x-x^2}}$.

Find the areas between the x-axis and each of the following curves, between the limits stated.

33. $y^2 = 1 + x^2y^2$; $x = 0$ to $x = 1/2$; $x = -1/2$ to $x = +1/2$.

34. $y + x^2y = 1$; $x = 0$ to $x = 1$; $x = 0$ to $x = a$.

35. $y^2 = 1 + 4x^2y^2$; $x = 0$ to $x = 1/4$; $x = -1/4$ to $x = +1/4$.

36. $4x^2y + y + 1 = 0$; $x = 1$ to $x = 2$; $x = -1$ to $x = +1$.

37. Show that the derivative of $\tan^{-1}[(e^x - e^{-x})/2]$ is $2/(e^x + e^{-x})$. [Note. The function $\tan^{-1}[(e^x - e^{-x})/2]$, or $\tan^{-1}(\sinh x)$, is called the ***Gudermannian*** of x and is denoted by ***gd x***: $\text{gd}\, x = \tan^{-1}(\sinh x)$. It follows from this exercise that $d\, \text{gd}\, x/dx = \text{sech}\, x$.]

38. From the fact that $d(\sinh x) = \cosh x\, dx$, show that the derivative of the ***inverse hyperbolic sine*** ($x = \sinh^{-1} u$ if $u = \sinh x$) is given by the equation $d(\sinh^{-1} u) = \pm du/\sqrt{1+u^2}$. [See foot of p. 108.]

39. Show that $d \cosh^{-1} u = \pm du/\sqrt{u^2-1}$.

40. Show that $d \tanh^{-1} u = du/(1-u^2)$.

80. Collection of Formulas for Differentiation. For convenience in reference we shall restate all of the formulas for differentiation, combining each of them with [VII] when it is desirable to do so.

I. $\dfrac{dc}{dx} = 0.$ II. $\dfrac{d\,c\cdot u}{dx} = c\dfrac{du}{dx}.$

III. $\dfrac{d\,(u+v)}{dx} = \dfrac{du}{dx} + \dfrac{dv}{dx}.$ IV. $\dfrac{d\,u^n}{dx} = nu^{n-1}\dfrac{du}{dx}.$

V. $\dfrac{d\left(\dfrac{N}{D}\right)}{dx} = \dfrac{D\dfrac{dN}{dx} - N\dfrac{dD}{dx}}{D^2}.$ VI. $\dfrac{d\,uv}{dx} = u\dfrac{dv}{dx} + v\dfrac{du}{dx}.$

VII. $\dfrac{dy}{dx} = \dfrac{dy}{du}\cdot\dfrac{du}{dx}.$ VIIa. $\dfrac{dy}{dx} = \dfrac{dy}{dt} \div \dfrac{dx}{dt}.$

VIII. $\dfrac{d\log_B u}{dx} = \dfrac{1}{u}\log_B e\cdot\dfrac{du}{dx}.$ VIIIa. $\dfrac{d\log u}{dx} = \dfrac{1}{u}\dfrac{du}{dx}.$

IX. $\dfrac{d\,B^u}{dx} = B^u\log B\cdot\dfrac{du}{dx}.$ IXa. $\dfrac{d\,e^u}{dx} = e^u\dfrac{du}{dx}.$

X. $\dfrac{d\sin u}{dx} = \cos u\dfrac{du}{dx}.$ XI. $\dfrac{d\cos u}{dx} = -\sin u\dfrac{du}{dx}.$

XII. $\dfrac{d\tan u}{dx} = \sec^2 u\dfrac{du}{dx}.$ XIII. $\dfrac{d\,\mathrm{ctn}\,u}{dx} = -\csc^2 u\dfrac{du}{dx}.$

XIV. $\dfrac{d\sec u}{dx} = \sec u\tan u\dfrac{du}{dx}.$ XV. $\dfrac{d\csc u}{dx} = -\csc u\,\mathrm{ctn}\,u\dfrac{du}{dx}.$

XVI, XVII. $\dfrac{d}{dx}\begin{Bmatrix}\sin^{-1}u\\ \cos^{-1}u\end{Bmatrix} = \dfrac{\pm 1}{\sqrt{1-u^2}}\dfrac{du}{dx}.$

XVIII, XIX. $\dfrac{d}{dx}\begin{Bmatrix}\tan^{-1}u\\ \mathrm{ctn}^{-1}u\end{Bmatrix} = \dfrac{\pm 1}{1+u^2}\dfrac{du}{dx}.$

XX, XXI. $\dfrac{d}{dx}\begin{Bmatrix}\sec^{-1}u\\ \csc^{-1}u\end{Bmatrix} = \dfrac{\pm 1}{u\sqrt{u^2-1}}\dfrac{du}{dx}.$

XXII. $\dfrac{d}{dx}\mathrm{vers}^{-1}u = \dfrac{1}{\sqrt{2u-u^2}}\dfrac{du}{dx}.$

CHAPTER X

APPLICATIONS TO CURVES

LENGTH — CURVATURE

81. Introduction. The formulas obtained in Chapters VIII and IX make possible many new applications to curves. We shall treat some of these in this Chapter.

82. Length of an Arc of a Curve. Let $s(x)$ denote the length of the arc of a given curve $y = f(x)$, from a fixed point F to a variable point P. When x increases by an amount Δx, let $\Delta s = \text{arc } PQ$ be the corresponding increase in s, and let $\Delta c = \text{chord } PQ$. Then

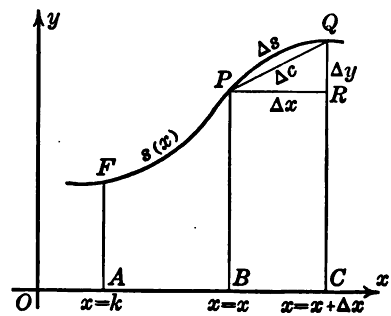

Fig. 29.

(1) $\overline{\Delta c}^2 = \overline{\Delta x}^2 + \overline{\Delta y}^2,$

whence

(2) $$\frac{\Delta c}{\Delta x} = \sqrt{1 + \left(\frac{\Delta y}{\Delta x}\right)^2},$$

and

(3) $$\frac{\Delta s}{\Delta x} = \sqrt{1 + \left(\frac{\Delta y}{\Delta x}\right)^2} \cdot \frac{\Delta s}{\Delta c}.$$

We now require the following ***fundamental axiom,*** which forms the basis of the mensuration of curved lines.

As the chord and its arc approach zero, their ratio approaches 1, *i.e.*

(4) $$\lim_{\Delta c \to 0} \frac{\Delta s}{\Delta c} = 1.$$

Combining (3) and (4), and passing to the limit as Δx approaches zero, we have

$$(5) \qquad \frac{ds}{dx} = \sqrt{1 + \left(\frac{dy}{dx}\right)^2} = \sqrt{1 + m^2},$$

where $m = dy/dx$ is the slope of the curve.

It follows that the total change in s between any two fixed points $x = a$ and $x = b$, is

$$(6) \qquad \textit{Total length} = s\Big]_{x=a}^{x=b} = \int_{x=a}^{x=b} \sqrt{1 + m^2}\, dx.$$

83. Parameter Forms. When the equation of a curve is given in parameter form

$$(1) \qquad x = f(t), \quad y = \phi(t),$$

we may square both sides of (5), § 82, and multiply by dx^2. This gives the formula

$$(2) \qquad ds^2 = dx^2 + dy^2,$$

which is called the ***Pythagorean differential formula.*** It is readily remembered by reference to the triangle PQR, Fig. 29. If we divide both sides of (2) by dt^2, we find *

$$(3) \qquad \left(\frac{ds}{dt}\right)^2 = \left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2.$$

From (3) we have

$$(4) \qquad \frac{ds}{dt} = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2},$$

whence

$$(5) \qquad s\Big]_{t=t_1}^{t=t_2} = \int_{t_1}^{t_2} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt,$$

whicn gives the length of the curve (1) between any two of its points.

* This expresses the fact that *the square of the total speed ds/dt is the sum of the squares of the horizontal speed dx/dt and the vertical speed dy/dt.* This fact, proved in § 40, might have been used as the point of departure, and all of the formulas of §§ 82–83 might have been deduced from it.

84. Illustrative Examples. While the square root which occurs in the formulas of §§ 82–83 renders the integrations rather difficult in general, the work is quite easy in some examples, as illustrated below.

EXAMPLE 1. Find the length of the curve $y^2 = x^3$ from the origin to the point where $x = 5$.

From $y^2 = x^3$ we find $y = x^{3/2}$, whence

$$\frac{dy}{dx} = \frac{3}{2}x^{1/2},\ ds = \sqrt{1 + \left(\frac{dy}{dx}\right)^2}dx = \sqrt{1 + \frac{9x}{4}}\,dx,$$

and

$$s\Big]_{x=0}^{x=5} = \int_0^5 \sqrt{1 + \frac{9x}{4}}\,dx = \frac{8}{27}\left(1 + \frac{9}{4}x\right)^{3/2}\Big]_{x=0}^{x=5} = \frac{335}{27}.$$

EXAMPLE 2. Find the length of the catenary (§ 67)

$$y = \frac{e^x + e^{-x}}{2}$$

from the origin to the point where $x = 1$.

We find immediately

$$\frac{dy}{dx} = \frac{e^x - e^{-x}}{2}, \qquad \frac{ds}{dx} = \left(1 + \left(\frac{e^x - e^{-x}}{2}\right)^2\right)^{1/2},$$

which reduces algebraically to the form

$$\frac{ds}{dx} = \left(\frac{e^{2x} + 2 + e^{-2x}}{4}\right)^{1/2} = \frac{e^x + e^{-x}}{2};$$

hence

$$s\Big]_{x=0}^{x=1} = \int_0^1 \frac{e^x + e^{-x}}{2}\,dx = \frac{e^x - e^{-x}}{2}\Big]_0^1 = \frac{1}{2}\left(e - \frac{1}{e}\right) - \frac{1}{2}(1 - 1)$$

$$= \frac{(2.718 - 0.368)}{2} = 1.175 \text{ (nearly).}$$

Compare § 67, and Tables III, E, and V, C.

EXAMPLE 3. Find the length of one arch of the cycloid (Tables III, G).

$$x = a\,(t - \sin t), \qquad y = a\,(1 - \cos t).$$

We find

$$dx = (a - a\cos t)\,dt, \qquad dy = a\sin t\,dt,$$

$$ds = \sqrt{dx^2 + dy^2} = a\sqrt{2 - 2\cos t}\,dt = 2\,a\sin\frac{t}{2}\,dt,$$

whence

$$s\Big]_{t=0}^{t=2\pi} = \int_0^{2\pi} 2\,a\sin\frac{t}{2}\,dt = -4\,a\cos\frac{t}{2}\Big]_0^{2\pi} = -4\,a\,[\cos\pi - \cos 0]$$

$$= -4\,a[-1 - 1] = 8\,a.$$

EXERCISES

Determine by integration the lengths of the following curves, each between the limits $x = 1$ to $x = 2$, $x = 2$ to $x = 4$, $x = a$ to $x = b$. Check the first three geometrically.

1. $y = 3x - 1$.
2. $y = 3 + 2x$.
3. $y = mx + c$.
4. $y = \frac{2}{3}(x - 1)^{3/2}$.
5. $y = \frac{1}{3}(2x - 1)^{3/2}$.
6. $y = \frac{1}{6}(4x - 1)^{3/2}$.

Find ds, the speed v, and the length s of the path of each of the following motions, between the given limits.

7. $x = 1 + t$, $y = 1 - t$; $t = 0$ to $t = 2$.

8. $x = (1 + t)^{3/2}$, $y = (1 - t)^{3/2}$; $t = 0$ to $t = 1$.

9. $x = (1 - t)^2$, $y = 8\,t^{3/2}/3$; $t = 0$ to $t = 9$.

10. $x = 1 + t^2$, $y = t - t^3/3$; $t = 0$ to $t = 5$.

11. $x = 2/t$, $y = t + 1/(3\,t^3)$; $t = a$ to $t = b$.

12. Find the length of the cycloid (Ex. 3, § 84) for half of one arch, *i.e.*, from $t = 0$ to $t = \pi$; for the portion from $t = 0$ to $t = \pi/2$; from $t = 0$ to $t = \pi/3$.

13. Show that the element of length for the cardioid (Tables III, G_4)

$$x = 2\,a\cos\theta - a\cos 2\,\theta,\quad y = 2\,a\sin\theta - a\sin 2\,\theta,$$

is

$$ds = 2\,a[2 - 2(\cos 2\,\theta\cos\theta + \sin 2\,\theta\sin\theta)]^{1/2}\,d\theta = 2\,a\,(2 - 2\cos\theta)^{1/2}d\theta.$$

Hence show that the entire length of the cardioid, from $\theta = 0$ to $\theta = 2\,\pi$ is $16\,a$. Show that the length of the part of the cardioid from $\theta = 0$ to $\theta = \pi/2$ is $4\,a\,(2 - \sqrt{2})$.

14. The equation of a circle about the origin may be replaced by the parameter equations

$$x = a\cos\theta, \qquad y = a\sin\theta,$$

where a is the radius. Hence find by integration the length of the entire circumference.

15. Show that the element of length of the four-cusped hypocycloid (Tables III, G_6)

$$x = a\cos^3\theta, \qquad y = a\sin^3\theta,$$

is

$$ds = 3\,a\sin\theta\cos\theta\,d\theta = \tfrac{3}{2}\,a\sin 2\,\theta\,d\theta.$$

Hence show that the length of one quarter of this curve is $3\,a/2$.

16. Show that the length of the general catenary

$$y = \frac{e^{ax} + e^{-ax}}{2a}$$

from the origin to any point $x = x$ is $(e^{ax} - e^{-ax})/2a$.

17. Writing the equation of the simple catenary in the form used in § 67, $y = \cosh x$, show that its length between the origin and any point $x = x$, is $\sinh x$.

85. Areas of Surfaces of Revolution. Consider the surface generated when the arc KL of the curve

(1) $$y = f(x)$$

(Fig. 30) revolves about the x-axis. Let us denote by $S(x)$ the area of the surface generated by the arc KP, and by ΔS the area of the surface generated by the arc $PQ = \Delta s$. If the curve rises from P to Q we may write, with entire accuracy,

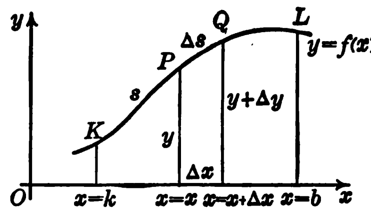

FIG. 30.

(2) $$2\pi y\,\Delta s \leqq \Delta S \leqq 2\pi(y + \Delta y)\,\Delta s.$$

Hence, dividing by Δx and passing to the limit, we may write

(3) $$\frac{dS}{dx} = 2\pi y\frac{ds}{dx} = 2\pi y\sqrt{1 + \left(\frac{dy}{dx}\right)^2},$$

whence the area of the surface of revolution from $x = a$ to $x = b$ is

(4) $$S\Big]_{x=a}^{x=b} = \int_a^b 2\pi y\frac{ds}{dx}\,dx = \int_a^b 2\pi y\sqrt{1 + \left(\frac{dy}{dx}\right)^2}\,dx.$$

Similarly, if the curve is revolved about the y-axis, the area between $y = c$ and $y = d$ is

(5) $$S\Big]_{y=c}^{y=d} = \int_c^d 2\pi x\frac{ds}{dy}\,dy = \int_c^d 2\pi y\sqrt{1 + \left(\frac{dx}{dy}\right)^2}\,dy.$$

Finally, if the equation of the curve is written in parameter form

$$x = f(t), \quad y = \phi(t),$$

we divide (2) by Δt, and let Δt approach zero, obtaining

$$(3') \qquad \frac{dS}{dt} = 2\pi y \frac{ds}{dt} = 2\pi y \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}. \qquad (§ 83.)$$

Hence the area of the surface of revolution formed by revolving the curve about the x-axis, between points at which $t = t_1$, and $t = t_2$, is

$$(6) \qquad S\Big]_{t=t_1}^{t=t_2} = \int_{t_1}^{t_2} 2\pi y\, ds = \int_{t_1}^{t_2} 2\pi y \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\, dt.$$

A similar formula can be written if the revolution is about the y-axis.

EXAMPLE 1. Find the surface of the cone generated when the segment of the straight line $y = x - 2$ from $x = 2$ to $x = 5$ revolves about the x-axis.

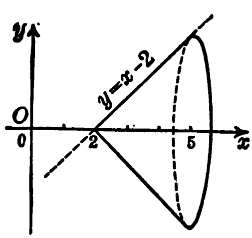

FIG. 31.

$$S\Big]_{x=2}^{x=5} = \int_2^5 2\pi y \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx$$

$$= \int_2^5 2\pi (x - 2)\sqrt{1 + 1}\, dx$$

$$= 2\pi\sqrt{2}\int_2^5 (x - 2)\, dx$$

$$= 2\pi\sqrt{2}\left(\frac{x^2}{2} - 2x\right)\Big]_2^5 = 9\pi\sqrt{2}.$$

Check this solution by finding the area of this cone by elementary geometry.

EXAMPLE 2. Find the area of the surface generated when the segment of the curve whose parameter equations are

$$x = \frac{1}{6}(4t + 1)^{3/2}, \qquad y = t^2 + 5$$

between $t = 1$ and $t = 2$ is rotated about the x-axis.

$$ds^2 = dx^2 + dy^2 = (4\,t + 1 + 4\,t^2)\,dt^2 = (2\,t + 1)^2\,dt^2$$

$$S = \int_{t=1}^{t=2} 2\,\pi\,y\,ds = 2\,\pi \int_1^2 (t^2 + 5)\,(2\,t + 1)\,dt$$

$$= 2\,\pi \left[\frac{t^4}{2} + \frac{t^3}{3} + 5\,t^2 + 5\,t\right]_1^2 = 2\,\pi\,[40\tfrac{2}{3} - 10\tfrac{5}{6}] = 59\tfrac{2}{3}\,\pi.$$

EXERCISES

Find the area of the surface generated by each of the following lines when revolved about the x-axis, from $x = 1$ to $x = 2$; from $x = 2$ to $x = 4$; from $x = a$ to $x = b$.

1. $y = 2\,x - 1$. **2.** $y = 3 + 4\,x$. **3.** $y = 3\,x + 2$.

Find the area of the surface generated by each of the following curves when revolved about the x-axis, between the limits indicated.

4. $y = \sqrt{1 - x^2}$; $x = 0$ to $x = 1$; $x = \frac{1}{2}$ to $x = 1$.

5. $y = \sqrt{4\,x - x^2}$; $x = 0$ to $x = 4$; $x = 1$ to $x = 3$.

6. $y = \sqrt{7 + 6\,x - x^2}$; $x = -1$ to $x = 7$; $x = 2$ to $x = 5$.

7. Find the area of the surface generated by rotating the arc of the catenary

$$y = \frac{e^x + e^{-x}}{2}$$

about the x-axis, between the points where $x = 0$ and $x = 1$.

8. Find the area of the surface generated by rotating the arc of the curve whose parameter equations are $x = 8\,t^{3/2}/3$, $y = (1 - t)^2$ about the x-axis, between the points where $t = 0$ and $t = 1$.

9. Find the area of the surface generated by the arc of the curve whose parameter equations are $x = \dfrac{2}{t}$, $y = t + 1/(3\,t^3)$ about the x-axis between the points where $t = 1$ and $t = 2$.

86. Curvature. A very important concept for any plane curve is its rate of bending, or curvature.

The *flexion* (§ 39, p. 61),

$$b = \frac{dm}{dx} = \frac{d^2y}{dx^2}, \tag{1}$$

is not a satisfactory measure of the bending; since it evidently depends upon the choice of axes, and changes when the axes are rotated, for example.

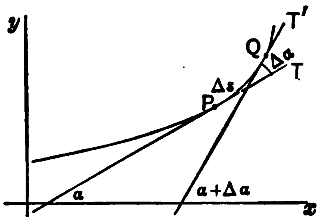

FIG. 32.

If we consider the rate of change of the inclination of the tangent, $\alpha = \tan^{-1} m$, with respect to the length of arc s, that is,

$$(2) \qquad \lim_{\Delta s \to 0} \frac{\Delta\alpha}{\Delta s} = \frac{d\alpha}{ds},$$

it is evident that we have a measure of bending which does not depend on the choice of axes, since $\Delta\alpha$ and Δs are the same, even though the axes are moved about arbitrarily, or, indeed, before any axes are drawn. The quantity $d\alpha/ds$ is called the ***curvature*** of the curve at the point P, and is denoted by the letter K: *the curvature is the instantaneous rate of change of α per unit length of arc.*

Since $\alpha = \tan^{-1} m$, and since $ds^2 = dx^2 + dy^2$ (§ 83, p. 134), we have,

$$d\alpha = d \tan^{-1} m = \frac{1}{1+m^2}\, dm, \quad ds = \sqrt{1+m^2}\, dx,$$

where $m = dy/dx$; hence the curvature K is

$$(3) \qquad K = \frac{d\alpha}{ds} = \frac{\dfrac{1}{1+m^2}\,dm}{\sqrt{1+m^2}\,dx} = \frac{\dfrac{dm}{dx}}{(1+m^2)^{3/2}} = \frac{b}{(1+m^2)^{3/2}},$$

where $b = d^2y/dx^2$ (= flexion), and $m = dy/dx$ (= slope). It appears therefore that the flexion b when multiplied by the corrective factor $1/(1+m^2)^{3/2}$ gives a satisfactory measure of the bending, since K is independent of the choice of axes.

The reciprocal of K grows larger as the curve becomes flatter; it is called the ***radius of curvature***, and is denoted by the letter R:

(4) $$R = \frac{1}{K} = \frac{ds}{d\alpha} = \frac{(1+m^2)^{3/2}}{b}.$$

It should be noticed that this concept agrees with the elementary concept of radius in the case of a circle, since $\Delta s = r\,\Delta\alpha$ in any circle of radius r. Hence $ds/d\alpha = r$.

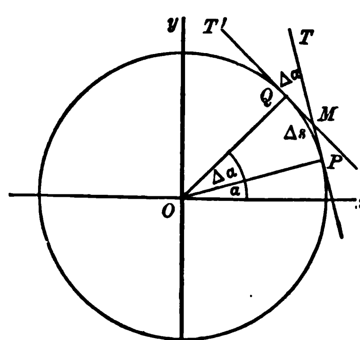

FIG. 33.

Substituting the values of b and m, formulas (3) and (4) may be written in the forms

(5) $$K = \frac{\dfrac{d^2y}{dx^2}}{\left[1+\left(\dfrac{dy}{dx}\right)^2\right]^{3/2}};$$

(6) $$R = \frac{\left[1+\left(\dfrac{dy}{dx}\right)^2\right]^{3/2}}{\dfrac{d^2y}{dx^2}}.$$

It is preferable, however, to calculate m and b first, and then substitute these values in (3) and (4).

Since $\sqrt{1+m^2} = \sec\alpha$ the formulas may also be written in the form $K = 1/R = b\cos^3\alpha$.

It is usual to consider only the ***numerical values*** of K, that is $|K|$, without regard to sign. Since K and b have the same sign, the value of K given by (3) will be negative when b is negative, *i.e.* when the curve is concave downwards (§ 41, p. 65). The same remarks apply to R, since $R = 1/K$.

87. Center of Curvature. Evolute of a Curve. The *center of curvature* Q of a curve, corresponding to a point P on that curve, is obtained by drawing the normal to the curve at P and laying off the distance R (the radius of curvature) along this normal from P toward the concave side of the curve. Thus, in Fig. 34, denoting the coordinates of P by (x, y), and those of Q by (α, β), we have

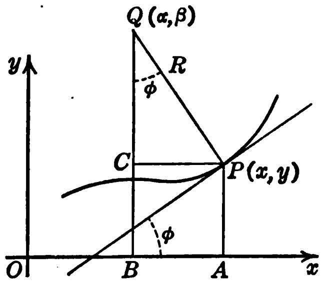

FIG. 34.

(1) $$\alpha = OB = OA - BA = x - R \sin \phi,$$

(2) $$\beta = BQ = AP + CQ = y + R \cos \phi,$$

where ϕ is the angle which the tangent PT makes with the x-axis,

(3) $$\tan \phi = m = \frac{dy}{dx},$$

whence

(4) $$\sin \phi = \frac{m}{\sqrt{1 + m^2}}, \quad \cos \phi = \frac{1}{\sqrt{1 + m^2}}.$$

It follows that we may write

(5) $$\alpha = x - \frac{m(1 + m^2)}{b}, \quad \beta = y + \frac{1 + m^2}{b},$$

where $$m = dy/dx, \quad b = d^2y/dx^2.$$

As the point P moves along the given curve, the point Q also describes a curve, which is called the *evolute* of the given curve. The parameter equations of the evolute are precisely the equations (5), in which (α, β) are the variable coordinates of the point on the evolute, x is a parameter, and y is to be replaced by its value in terms of x from the equation of the given curve.

In particular examples, it is possible to eliminate the parameter x between the two equations (5) after having substituted for y, m, and b their values found from the equation of the given curve. This gives the equation of the evolute as a single equation between the variables α and β.

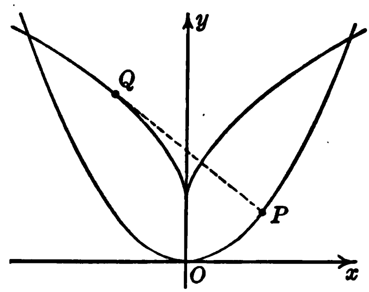

FIG. 35.

EXAMPLE 1. Find the values of K, R, α, β, and find the equation of the evolute for the curve $y = x^2/4$.

Here $m = x/2$, $b = 1/2$. Hence

$$K = \frac{1/2}{(1 + x^2/4)^{3/2}} = \frac{4}{(4 + x^2)^{3/2}},$$

$$R = \frac{1}{K} = \frac{(4 + x^2)^{3/2}}{4},$$

$$\alpha = x - \frac{x}{2}\frac{1 + x^2/4}{1/2} = -\frac{x^3}{4},$$

$$\beta = y + \frac{1 + x^2/4}{1/2} = \frac{x^2}{4} + 2 + \frac{x^2}{2} = \frac{3\,x^2}{4} + 2.$$

Eliminating x between the last two equations, we find the equation of the evolute in the variables α and β,

$$27\,\alpha^2 = 4\,(\beta - 2)^3.$$

EXAMPLE 2. Find the values of K, R, α, β, and the parameter equations of the evolute for the cycloid

$$x = a\,(\theta - \sin\theta),\ y = a\,(1 - \cos\theta).$$

$$m = \frac{dy}{dx} = \frac{dy/d\,\theta}{dx/d\,\theta} = \frac{a\sin\theta}{a\,(1 - \cos\theta)} = \operatorname{ctn}\frac{\theta}{2},$$

$$b = \frac{dm}{dx} = \frac{dm/d\,\theta}{dx/d\,\theta} = \frac{-1}{a\,(1 - \cos\theta)^2} = \frac{-1}{4\,a\sin^4\dfrac{\theta}{2}},$$

$$|K| = \left|\frac{-1}{4\,a\sin^4\dfrac{\theta}{2}} \div \left(1 + \operatorname{ctn}^2\frac{\theta}{2}\right)^{3/2}\right| = \frac{1}{4\,a\sin\dfrac{\theta}{2}},$$

$$R = \frac{1}{|K|} = 4\,a \sin\frac{\theta}{2},$$

$$\alpha = a\,(\theta - \sin\theta) + \operatorname{ctn}\frac{\theta}{2}\,\frac{1 + \operatorname{ctn}^2\frac{\theta}{2}}{\dfrac{1}{4\,a\sin^4\frac{\theta}{2}}} = a\,(\theta + \sin\theta),$$

$$\beta = a\,(1 - \cos\theta) - \frac{1 + \operatorname{ctn}^2\frac{\theta}{2}}{\dfrac{1}{4\,a\sin^4\frac{\theta}{2}}} = -\,a\,(1 - \cos\theta).$$

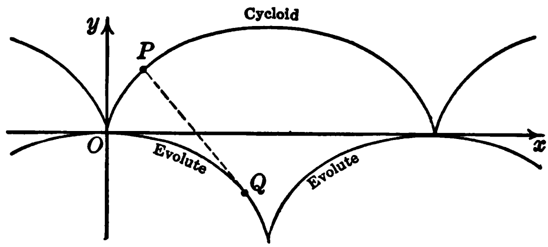

FIG. 36.

These equations for α and β are the parameter equations of the evolute; they represent a new cycloid, similar to the given one, but situated as shown in Fig. 36.

EXERCISES

Calculate K, R, α, β for each of the following curves; sketch the curve and its evolute:

1. $y = x^2$. **2.** $y = x^3$. **3.** $y^2 = 4\,ax$.

4. $xy = a^2$. **5.** $y = \sin x$. **6.** $y = e^x$.

7. $y = (e^x + e^{-x})/2 = \cosh x$. **8.** $y = (e^x - e^{-x})/2 = \sinh x$.

9. $x^2/a^2 + y^2/b^2 = 1$. **10.** $x^2/a^2 - y^2/b^2 = 1$.

11. $\sqrt{x} + \sqrt{y} = \sqrt{a}$. **12.** $x^{2/3} + y^{2/3} = a^{2/3}$.

13. $\begin{cases} x = a\cos\theta, \\ y = a\sin\theta. \end{cases}$ **14.** $\begin{cases} x = \sin\theta, \\ y = 2\cos\theta. \end{cases}$ **15.** $\begin{cases} x = a\cos^3\theta, \\ y = a\sin^3\theta. \end{cases}$

16. $\begin{cases} x = t^2, \\ y = t - t^3/3. \end{cases}$ **17.** $\begin{cases} x = 1/t, \\ y = t. \end{cases}$ **18.** $\begin{cases} x = \sec t, \\ y = \tan t. \end{cases}$

19. $\begin{cases} x = 2 + 3\,t, \\ y = t^2 - 4. \end{cases}$ **20.** $\begin{cases} x = \cos t + t\sin t, \\ y = \sin t - t\cos t. \end{cases}$

88. Properties of the Evolute. If the point $P(x, y)$ lies on a curve $y = f(x)$, and the point $Q(\alpha, \beta)$ is the corresponding point of the evolute, we have

$$\alpha = x - \frac{m + m^3}{b}, \qquad \beta = y + \frac{1 + m^2}{b}.$$

Let m' be the slope of the evolute at Q; then

$$m' = \frac{d\beta}{d\alpha} = \frac{d\beta/dx}{d\alpha/dx}.$$

But we have

$$\begin{aligned}\frac{d\beta}{dx} &= m + \frac{b \cdot 2\,mb - (1 + m^2)\,db/dx}{b^2} \\ &= \frac{3\,mb^2 - (1 + m^2)\,db/dx}{b^2}, \\ \frac{d\alpha}{dx} &= 1 - \frac{b\,(1 + 3\,m^2)\,b - (m + m^3)\,db/dx}{b^2} \\ &= \frac{-\,3\,m^2b^2 + (m + m^3)\,db/dx}{b^2}.\end{aligned}$$

It follows that

$$m' = \frac{d\beta}{d\alpha} = -\frac{1}{m}.$$

Hence the normal to the curve at P is the tangent to its evolute at Q. Hence the radius of curvature of the curve at C is tangent to the evolute at Q. (See Fig. 35.)

89. Length of the Evolute. As Q moves along on the evolute, the rate of change of R is the rate of change of the arc of the evolute. For, since we have, in Fig. 34,

(1) $$R^2 = \overline{PQ}^2 = (x - \alpha)^2 + (y - \beta)^2,$$

it follows that

(2) $$R\,dR = (x - \alpha)\,(dx - d\alpha) + (y - \beta)\,(dy - d\beta).$$

But we have

$$m = \frac{dy}{dx} = -\frac{x - \alpha}{y - \beta}, \quad \text{or} \quad (x - \alpha)\,dx + (y - \beta)\,dy = 0.$$

Hence (2) may be written in the form

$$(3)\qquad dR = \frac{(x-\alpha)\,d\alpha + (y-\beta)\,d\beta}{\sqrt{(x-\alpha)^2 + (y-\beta)^2}}.$$

By § 88, we have

$$\frac{d\beta}{d\alpha} = -\frac{1}{m} = \frac{y-\beta}{x-\alpha}.$$

Substituting this in (3), we find

$$(4)\quad dR = \frac{d\alpha + \dfrac{y-\beta}{x-\alpha}\,d\beta}{\sqrt{1+\left(\dfrac{y-\beta}{x-\alpha}\right)^2}} = \frac{d\alpha + \dfrac{d\beta}{d\alpha}\,d\beta}{\sqrt{1+\left(\dfrac{d\beta}{d\alpha}\right)^2}} = \sqrt{d\alpha^2 + d\beta^2}.$$

This result, however, is precisely ds, where s is the length of the arc of the evolute. Hence we have

$$(5)\quad dR = ds, \text{ or } \int_{R=R_1}^{R=R_2} dR = \int_{s=s_1}^{s=s_2} ds, \text{ or } R_2 - R_1 = s_2 - s_1;$$

that is: the rate of growth of the radius of curvature is equal to the rate of growth of the arc of the evolute; and the difference between two radii of curvature is the same as the length of the arc of the evolute which separates them.

This fact gives rise to an interesting method of drawing the original curve (the involute) from the evolute: Imagine a string wound along the convex portion of the evolute, fastened at some point (say Q, Fig. 35, p. 143) and then stretched taut. If a pencil is inserted at any point (say P, Fig. 35) in the string, the pencil will traverse the involute as the string, still held taut, is unwound from the evolute.

As exercises, the lengths of the portions of the evolutes of curves given in the preceding list of exercises may be found.

CHAPTER XI

POLAR COORDINATES

90. Introduction. Since the equations of curves in polar coordinates often involve trigonometric functions, the equations of curves have been written in rectangular coordinates throughout the earlier part of this book. We shall now show how to extend many of the results already found for curves whose equations are written in rectangular coordinates to curves whose equations are written in polar coordinates.

91. Angle between Radius Vector and Tangent. Let C (Fig. 37) be a curve whose equation in polar coordinates is

(1) $$\rho = f(\theta).$$

Consider the angle ψ between the radius vector OPR and the tangent PT to C at P. Let Q be a second point on C, with coordinates $\rho + \Delta\rho$, $\theta + \Delta\theta$, and let ϕ be the angle

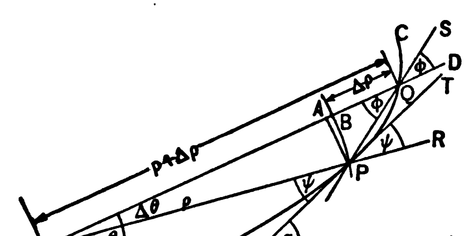

FIG. 37.

between the radius vector OQD and the secant PQS. As $\Delta\theta$ approaches zero, *i.e.* as Q approaches P along C, we shall have

(2) $$\psi = \lim_{\Delta\theta \to 0} \phi, \text{ and } \tan \psi = \lim_{\Delta\theta \to 0} \tan \phi.$$

Draw AP perpendicular to OQ; then we shall have

$$(3)\quad \tan\phi = \frac{AP}{AQ} = \frac{AP}{OQ - OA} = \frac{\rho\sin\Delta\theta}{\rho + \Delta\rho - \rho\cos\Delta\theta},$$

and

$$(4)\quad \tan\psi = \lim_{\Delta\theta\to 0}\frac{\rho\sin\Delta\theta}{\rho + \Delta\rho - \rho\cos\Delta\theta} = \lim_{\Delta\theta\to 0}\frac{\rho\sin\Delta\theta}{\rho(1 - \cos\Delta\theta) + \Delta\rho}.$$

To evaluate this limit, divide both numerator and denominator by $\Delta\theta$ and note that

$$(5)\qquad \lim_{\Delta\theta\to 0}\frac{\sin\Delta\theta}{\Delta\theta} = 1,$$

and

$$(6)\qquad \lim_{\Delta\theta\to 0}\frac{1 - \cos\Delta\theta}{\Delta\theta} = \lim_{\Delta\theta\to 0}\frac{2\sin^2\frac{\Delta\theta}{2}}{\Delta\theta}$$

$$= \lim_{\Delta\theta\to 0}\left[\sin\frac{\Delta\theta}{2}\cdot\frac{\sin\frac{\Delta\theta}{2}}{\frac{\Delta\theta}{2}}\right] = 0\cdot 1 = 0.$$

It follows that

$$(7)\qquad \tan\psi = \lim_{\Delta\theta\to 0}\frac{\rho\dfrac{\sin\Delta\theta}{\Delta\theta}}{\rho\cdot\dfrac{1 - \cos\theta}{\Delta\theta} + \dfrac{\Delta\rho}{\Delta\theta}} = \frac{\rho}{\dfrac{d\rho}{d\theta}},$$

and therefore

$$(8)\qquad \tan\psi = \frac{\rho}{\dfrac{d\rho}{d\theta}} = \rho\frac{d\theta}{d\rho}.$$

The angle α between the x-axis and the tangent PT can be found, after ψ has been found, by means of the relation

$$(9)\qquad \alpha = \theta + \psi.$$

EXAMPLE 1. Given the curve $\rho = e^{\theta}$, to find $\tan \psi$, and ψ itself.

Since $\rho = e^{\theta}$, $d\rho/d\,\theta = e^{\theta}$, and $\tan \psi = \rho \div (d\rho/d\,\theta) = 1$. Hence $\psi = \tan^{-1} 1 = \pi/4 = 45°$. It follows that this curve cuts every radius vector at the fixed angle of 45°.

EXAMPLE 2. Given the curve $\rho = \sin 2\,\theta$, find ψ at the point where $\theta = \pi/8$.

$$\tan \psi = \rho \div (d\rho/d\,\theta) = \sin 2\,\theta \div 2 \cos 2\,\theta = (1/2) \tan 2\,\theta.$$

When $\theta = \pi/8$, $\tan \psi = 1/2$, and $\psi = 26°\,34'$, approximately.

EXERCISES

Plot each of the following curves in polar coordinates; find the value of $\tan \psi$ in general, and the value of ψ in degrees when $\theta = 0$, $\pi/6$, $\pi/4$, $\pi/2$, π.

1. $\rho = 4 \sin \theta$.
2. $\rho = 6 \cos \theta - 5$.
3. $\rho = 3 + 4 \cos \theta$.
4. $\rho = \tan \theta$.
5. $\rho = 2 + \tan^2 \theta$.
6. $\rho = \theta$.
7. $\rho = \theta^2$.
8. $\rho = 1/\theta$.
9. $\rho = e^{2\theta}$.
10. $\rho = e^{-4\theta}$.
11. $\rho = \sin 3\,\theta$.
12. $\rho = 2 \cos 3\,\theta$.
13. $\rho = 3 \sin (3\,\theta + 2\,\pi/3)$.
14. $\rho = 3 \cos \theta + 4 \sin \theta$.
15. $\rho = 2/(1 - \cos \theta)$.
16. Show that $\tan \psi$ is constant for the curve $\rho = ke^{a\theta}$.

Find $\tan \psi$ for each of the following curves:

17. $\rho = p/(1 - e \cos \theta)$ (conic).
18. $\rho = a \sec \theta \pm b$ (conchoid).
19. $\rho = a\,(1 + \cos \theta)$ (cardioid).
20. $\rho^2 = 2\,a^2 \cos 2\,\theta$ (lemniscate).

92. Areas in Polar Coordinates. Let KL be an arc of a curve whose equation in polar coördinates is

$$\rho = f(\theta). \tag{1}$$

Consider first the area of the sector OKP bounded by the radius vector OK, for which $\theta = \theta_1$, any other radius vector OP for which $\theta = \theta$, and the intercepted arc KP of the curve. The area is a function of the angle θ; let us denote it by $A(\theta)$.

Now let θ increase by an amount $\Delta\theta = \angle POQ$, and let PS and TQ be circular arcs whose radii are $\rho\,(= OP)$ and $\rho + \Delta\rho\,(= OQ)$, respectively. Then we shall have

$$\text{(2)} \qquad \text{sector } POS < \text{sector } POQ < \text{sector } TOQ,$$

if ρ increases with θ. If ρ decreases when θ increases, the inequality signs must be reversed in (2) and in what follows.

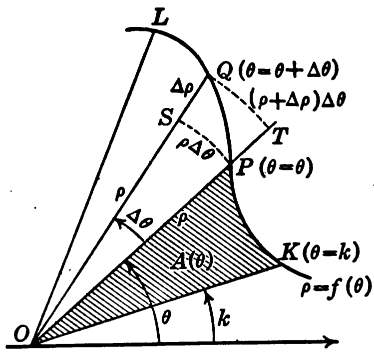

FIG. 38.

The area of any circular sector is equal to half the product of the angle (in circular measure) and the square of the radius. The sector POQ is the amount of increase in the area A; let us call it $\Delta A\,(\theta)$. Then (2) becomes

$$\text{(3)} \qquad \frac{\rho^2\,\Delta\theta}{2} < \Delta A\,(\theta) < \frac{(\rho + \Delta\rho)^2\,\Delta\theta}{2}.$$

Dividing through by $\Delta\theta$, we have

$$\text{(4)} \qquad \frac{\rho^2}{2} < \frac{\Delta A\,(\theta)}{\Delta\theta} < \frac{(\rho + \Delta\rho)^2}{2},$$

whence

$$\text{(5)} \qquad \lim_{\Delta\theta \to 0} \frac{\Delta A\,(\theta)}{\Delta\theta} = \frac{\rho^2}{2}, \quad \text{or} \quad \frac{dA}{d\theta} = \frac{\rho^2}{2}.$$

It follows that the area of the sector bounded by the curve and the radii vectores for which $\theta = \theta_1$, and $\theta = \theta_2$, respectively, is given by the formula

$$\text{(6)} \qquad A\Big]_{\theta_1}^{\theta_2} = \frac{1}{2}\int_{\theta_1}^{\theta_2} \rho^2\, d\theta.$$

EXAMPLE 1. Find the area of the sector bounded by the curve $\rho = 1/\theta$ and by the radii corresponding to $\theta = \pi/3$ and $\theta = \pi/2$.

The curve may be plotted readily by taking corresponding values of ρ and θ, as in the following table.

θ	0	$\pi/6$	$\pi/3$	$\pi/2$	$2\pi/3$	$5\pi/6$	π	etc.
ρ	∞	1.91	0.95	0.64	0.47	0.38	0.32	etc.

The required area is

$$A\Big]_{\theta=\pi/3}^{\theta=\pi/2} = \frac{1}{2}\int_{\pi/3}^{\pi/2}\frac{d\theta}{\theta^2}$$

$$= -\frac{1}{2}\theta^{-1}\Big]_{\pi/3}^{\pi/2}$$

$$= -\frac{1}{2}\left[\left(\frac{\pi}{2}\right)^{-1} - \left(\frac{\pi}{3}\right)^{-1}\right]$$

$$= \frac{1}{2\pi} = 0.16+.$$

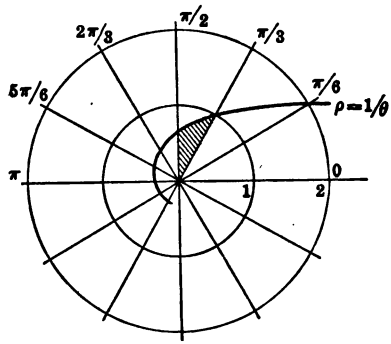

FIG. 39.

EXAMPLE 2. Find the area of the sector bounded by the curve $\rho = \tan\theta$, and by the radii corresponding to $\theta = 45°$ and $\theta = 60°$.

$$A\Big]_{45°}^{60°} = \frac{1}{2}\int_{\pi/4}^{\pi/3}\rho^2\,d\theta = \frac{1}{2}\int_{\pi/4}^{\pi/3}\tan^2\theta\,d\theta = \frac{1}{2}\int_{\pi/4}^{\pi/3}(\sec^2\theta - 1)\,d\theta$$

$$= \frac{1}{2}(\tan\theta - \theta)\Big|_{\pi/4}^{\pi/3} = \frac{1}{2}\left[(\sqrt{3} - \pi/3) - (1 - \pi/4)\right]$$

$$= \frac{1}{2}(\sqrt{3} - 1 - \pi/12) = .2351+$$

EXERCISES

Calculate the area formed by each of the following curves and the indicated radii, and check graphically.

1. $\rho = \theta$; $\theta = 0$ to π.
2. $\rho = 6/\theta^2$; $\theta = \pi/3$ to $\pi/2$.
3. $\rho = \sqrt{\theta}$; $\theta = \pi$ to 2π.
4. $\rho = \sqrt[3]{\theta}$; $\theta = 0$ to 2π.
5. $\rho = 4/\sqrt[3]{\theta}$; $\theta = \pi/8$ to π.
6. $\rho = 1 + \sqrt{\theta}$; $\theta = \pi/4$ to π.
7. $\rho = \sqrt{1+\theta}$; $\theta = 1$ to 3.
8. $\rho = \sqrt{1+\theta^2}$; $\theta = 0$ to 3.

9. $\rho = (\theta - 1)^2$; $\theta = 1$ to 6. **10.** $\rho = (1+\theta)/\theta^2$; $\theta = 180°$ to $360°$

11. $\rho = \sin\theta$; $\theta = 0$ to $\pi/2$. **12.** $\rho = \cos\theta$; $\theta = \pi$ to 2π.

13. $\rho = \sec\theta$; $\theta = \pi/4$ to $\pi/3$. **14.** $\rho = 1 + \sin\theta$; $\theta = 0$ to $\pi/2$.

Find the area bounded by each of the following curves:

15. $\rho = 4\cos\theta$. **16.** $\rho = 4\cos 2\theta$.

17. $\rho^2 = 4\cos 2\theta$. **18.** $\rho = 1 - \sin\theta$.

93. Lengths of Curves in Polar Coordinates. Let the equation of a curve in polar coordinates be

(1) $$\rho = f(\theta),$$

and let s denote the length of arc from a fixed point K to a variable point P. Then s is a function of θ. We shall show first how to obtain $ds/d\theta$, whence we may proceed to find s itself by an integration.

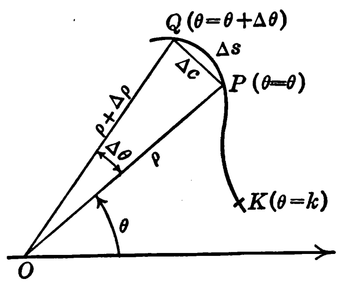

Fig. 40.

Let the coordinates of P be (ρ, θ), and those of a second point Q be $(\rho + \Delta\rho, \theta + \Delta\theta)$. Denote the arc PQ by Δs, and the chord PQ by Δc. Then from the identity

(2) $$\frac{\Delta s}{\Delta\theta} = \frac{\Delta s}{\Delta c}\cdot\frac{\Delta c}{\Delta\theta}$$

we find

(3) $$\frac{ds}{d\theta} = \lim_{\Delta\theta\to 0}\frac{\Delta s}{\Delta\theta} = \lim_{\Delta\theta\to 0}\frac{\Delta s}{\Delta c}\cdot\frac{\Delta c}{\Delta\theta} = \lim_{\Delta\theta\to 0}\frac{\Delta c}{\Delta\theta}. \quad \text{See (4), § 82.}$$

From the law of cosines,

$$\begin{aligned}\Delta c &= \sqrt{\rho^2 + (\rho+\Delta\rho)^2 - 2\rho(\rho+\Delta\rho)\cos\Delta\theta}\\ &= \sqrt{2(\rho^2 + \rho\Delta\rho)(1-\cos\Delta\theta) + \overline{\Delta\rho}^2}.\end{aligned}$$

It follows that

(4) $$\frac{\Delta c}{\Delta\theta} = \sqrt{(\rho^2 + \rho\Delta\rho)\cdot\frac{2(1-\cos\Delta\theta)}{\overline{\Delta\theta}^2} + \left(\frac{\Delta\rho}{\Delta\theta}\right)^2}.$$

But we have *

(5) $$\lim_{\Delta\theta\to 0}\frac{2(1-\cos\Delta\theta)}{\overline{\Delta\theta}^2} = 1 \text{ and } \lim_{\Delta\to 0}\frac{\Delta\rho}{\Delta\theta} = \frac{d\rho}{d\theta}.$$

Hence, by (3) and (4),

(6) $$\frac{ds}{d\theta} = \sqrt{\rho^2 + \left(\frac{d\rho}{d\theta}\right)^2}.$$

Integrating both sides of equation (6) with respect to θ, we find the important formula

(7) $$s\Big]_a^b = \int_{\theta=a}^{\theta=b}\sqrt{\rho^2 + \left(\frac{d\rho}{d\theta}\right)^2}\,d\theta.$$

Equation (6) may be supplied by squaring both sides and then multiplying both sides by $(d\theta)^2$. The resulting formula

(8) $$ds^2 = \rho^2\,d\theta + d\rho^2$$

is the Pythagorean differential formula in polar coordinates. (See § 83.)

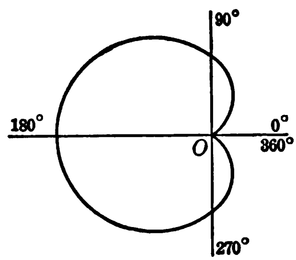

FIG. 41

EXAMPLE. Find the length of the curve $\rho = 1 - \cos\theta$.

$$d\rho = \sin\theta\,d\theta.$$
$$ds/d\theta = \sqrt{(d\rho/d\theta)^2 + \rho^2}.$$
$$= \sqrt{\sin^2\theta + (1-\cos\theta)^2}.$$
$$= \sqrt{2\,(1-\cos\theta)} = 2\sin(\theta/2).$$

The complete curve is traced when θ varies from 0 to $2\,\pi$. Hence

$$s\Big]_0^{2\pi} = \int_0^{2\pi} 2\sin(\theta/2)\,d\,\theta = -4\cos\frac{\theta}{2}\Big]_0^{2\pi} = 8.$$

* See and compare (6), p. 148. In this case we have

$$\frac{2\,(1-\cos\Delta\theta)}{\overline{\Delta\theta}^2} = \frac{4\sin^2\dfrac{\Delta\theta}{2}}{\overline{\Delta\theta}^2} = \left(\frac{\sin\dfrac{\Delta\theta}{2}}{\dfrac{\Delta\theta}{2}}\right)^2.$$

EXERCISES

Find the length of each of the following curves, or of the portion specified.

1. $\rho = 5 \sin \theta$.
2. $\rho = 3 \cos \theta$.
3. $\rho = e^{\theta}$; $\theta = 0$ to $\pi/2$.
4. $\rho = e^{a\theta}$; $\theta = 0$ to π.
5. $\rho = \sec \theta$; $\theta = \frac{1}{2}$ to 1.
6. $\rho = a \csc \theta$; $\theta = 45°$ to $90°$.
7. $\rho = \sin \theta + \cos \theta$; $\theta = 0$ to π.
8. $\log \rho = \theta$; $\theta = 2$ to 3.
9. $\log \rho = 3 + 2\theta$; $\theta = 0$ to 1.
10. $\rho = 1 + \sin \theta$.

94. Curvature in Polar Coordinates. By the definition of the curvature K of any curve (§ 86), we have

$$K = \frac{d\alpha}{ds} = \frac{d\alpha/d\theta}{ds/d\theta}. \tag{1}$$

Since $\alpha = \theta + \psi$ (§ 91), we have $d\alpha/d\theta = 1 + d\psi/d\theta$. Denoting $d\rho/d\theta$ by ρ' and $d^2\rho/d\theta^2$ by ρ'', we have

$$\psi = \tan^{-1} \frac{\rho}{\rho'}, \tag{2}$$

$$\frac{d\psi}{d\theta} = \frac{d}{d\theta} \tan^{-1} \frac{\rho}{\rho'} = \frac{1}{1 + (\rho/\rho')^2} \cdot \frac{d}{d\theta}\left(\frac{\rho}{\rho'}\right) \tag{3}$$

$$= \frac{1}{1 + (\rho/\rho')^2} \cdot \frac{\rho'^2 - \rho\rho''}{\rho'^2} = \frac{\rho'^2 - \rho\rho''}{\rho^2 + \rho'^2}.$$

It follows that

$$\frac{d\alpha}{d\theta} = 1 + \frac{d\psi}{d\theta} = 1 + \frac{\rho'^2 - \rho\rho''}{\rho^2 + \rho'^2} = \frac{\rho^2 + 2\rho'^2 - \rho\rho''}{\rho^2 + \rho'^2}. \tag{4}$$

Also, from (6), § 93,

$$\frac{ds}{d\theta} = \sqrt{\rho^2 + \rho'^2}. \tag{5}$$

Hence we have

$$K = \frac{d\alpha/d\theta}{ds/d\theta} = \frac{\rho^2 + 2\rho'^2 - \rho\rho''}{[\rho^2 + \rho'^2]^{3/2}}. \tag{6}$$

EXAMPLE 1. Find the curvature for any point on the curve $\rho = e^{2\theta}$. Since $\rho' = d\rho/d\theta = 2e^{2\theta}$, and $\rho'' = d^2\rho/d\theta^2 = 4e^{2\theta}$, we have

$$K = \frac{e^{4\theta} + 8e^{4\theta} - 4e^{4\theta}}{(e^{4\theta} + 4e^{4\theta})^{3/2}} = \frac{1}{\sqrt{5}\,e^{2\theta}}.$$

EXAMPLE 2. Find the curvature at any point of the circle $\rho = a \sin \theta$. Here we find $\rho' = a \cos \theta$, and $\rho'' = -a \sin \theta$. Therefore

$$K = \frac{a^2 \sin^2 \theta + 2\, a^2 \cos^2 \theta + a^2 \sin^2 \theta}{(a^2 \sin^2 \theta + a^2 \cos^2 \theta)^{3/2}}$$
$$= \frac{2\, a^2 (\sin^2 \theta + \cos^2 \theta)}{a^3 (\sin^2 \theta + \cos^2 \theta)^{3/2}} = \frac{2}{a}.$$

This is the reciprocal of the radius. (§ 86.)

EXERCISES

Find the radius of curvature of each of the following curves:

1. $\rho = e^\theta$.
2. $\rho = a^\theta$.
3. $\rho\theta = a$.
4. $\rho = \cos \theta$.
5. $\rho = \sin 3\, \theta$.
6. $\rho = a \sec 2\, \theta$.
7. $\rho = a(1 + \cos \theta)$.
8. $\rho = 2/(1 + \cos \theta)$.
9. $\rho = a + b \cos \theta$.

CHAPTER XII

TECHNIQUE OF INTEGRATION

95. Question of Technique. Collection of Formulas. The discovery of indefinite integrals as reversed differentials was treated briefly, for certain algebraic functions, in Chapter VII. We proceed to show how to integrate a variety of functions, but the majority are referred to ***tables of integrals***, since no list can be exhaustive. See *Tables*, IV, A–H.

To every differential formula (pp. 44, 132) there corresponds a formula of integration:

$$\text{if} \quad d\phi(x) = f(x)\,dx, \quad \text{then} \quad \int f(x)\,dx = \phi(x) + C.$$

The numbers assigned to the following formulas correspond to the number of the differential formula from which they come. Certain omitted numbers correspond to relatively unimportant formulas.

FUNDAMENTAL INTEGRALS

[I]$_i$ If $\dfrac{dy}{dx} = 0$, then y = constant. [See § 52, p. 86.]

[The arbitrary constant C in each of the other rules results from this rule.]

[II]$_i$ $$\int k\,f(x)\,dx = k\int f(x)\,dx.$$

[III]$_i$ $$\int \{f(x) + \phi(x)\}\,dx = \int f(x)\,dx + \int \phi(x)\,dx.$$

[IV]$_i$ $$\int x^n\,dx = \frac{x^{n+1}}{n+1} + C, \text{ when } n \neq -1. \quad \text{(See VIII.)}$$

[VI]ᵢ $$uv = \int d(uv) = \int u\,dv + \int v\,du. \quad [\text{“Parts”}]$$

[The corresponding formula [V]ᵢ for quotients is seldom used. See § 103.]

[VII]ᵢ $$\left.\int f(u)\,du\right]_{u=\phi(x)} = \int f[\phi(x)]\,d\phi(x)$$

$$[\text{Substitution}] \qquad = \int f[\phi(x)]\frac{d\phi(x)}{dx}\,dx.$$

[VIII]ᵢ $$\int \frac{dx}{x} = \log x + C.$$ [IX]ᵢ $$\int e^x\,dx = e^x + C.$$

[X]ᵢ $$\int \cos x\,dx = \sin x + C.$$ [XI]ᵢ $$\int \sin x\,dx = -\cos x + C.$$

[XII]ᵢ $$\int \sec^2 x\,dx = \tan x + C.$$

[XIII]ᵢ $$\int \csc^2 x\,dx = -\operatorname{ctn} x + C.$$

[XIV]ᵢ $$\int \sec x \tan x\,dx = \sec x + C.$$

[XV]ᵢ $$\int \csc x \operatorname{ctn} x\,dx = -\csc x + C.$$

[XVI]ᵢ $$\int \frac{dx}{\sqrt{1-x^2}} = \sin^{-1} x + C = -\cos^{-1} x + C'.$$ [XVII]ᵢ

[XVIII]ᵢ $$\int \frac{dx}{1+x^2} = \tan^{-1} x + C = -\operatorname{ctn}^{-1} x + C'.$$ [XIX]ᵢ

[XX]ᵢ $$\int \frac{dx}{x\sqrt{x^2-1}} = \sec^{-1} x + C = -\csc^{-1} x + C'.$$ [XXI]ᵢ

[XXII]ᵢ $$\int \frac{dx}{\sqrt{2x-x^2}} = \operatorname{vers}^{-1} x + C$$

The remaining differential formulas referred to on p. 132 give rise to other integral formulas; these will be found in the short ***table of integrals***, *Tables*, IV, A–H.

96. Polynomials. Other Simple Forms. The rules [II], [III], [IV] are evidently sufficient without further explanation to integrate any polynomials and indeed many simple radical expressions. This work has been practiced in Chapter VII extensively.

Attention is called especially to the fact that the rules [II] and [III] show that integration of a sum is in general simpler than integration of a product or a quotient. If it is possible, a product or a quotient should be replaced by a sum unless the integration can be performed easily otherwise. Thus the integrand $(1 + x^2)/x$ should be written $1/x + x$; $(1 + x^2)^2$ should be written $1 + 2x^2 + x^4$; and so on. This principle appears frequently in what follows.

97. Substitution. Use of [VII]. As we have already done in simple cases in Chapters VII and VIII, substitution of a new letter may be used extensively, based on Rule [VII].

EXAMPLE 1. To find $\int \frac{dx}{\sqrt{a^2 - x^2}}$.

Set $u = x/a$, then $du = dx/a$, or $dx = a\,du$, and

$$\int \frac{dx}{\sqrt{a^2 - x^2}} = \int \frac{a\,du}{\sqrt{a^2 - a^2u^2}} = \int \frac{du}{\sqrt{1 - u^2}} = \sin^{-1} u + C = \sin^{-1}\frac{x}{a} + C.$$

CHECK. $$d \sin^{-1}\frac{x}{a} = \frac{1}{\sqrt{1 - \frac{x^2}{a^2}}}\, d\left(\frac{x}{a}\right) = \frac{dx/a}{\sqrt{1 - \frac{x^2}{a^2}}} = \frac{dx}{\sqrt{a^2 - x^2}}$$

EXAMPLE 2. To find $\int \sin 2x\,dx$.

METHOD 1. *Direct Substitution.*

$$\int \sin 2x\,dx = \tfrac{1}{2}\int \sin(2x)\,d(2x) = -\tfrac{1}{2}[\cos 2x + C]$$
$$= -\tfrac{1}{2}\cos 2x + C'.$$

Check. $$d\left(-\tfrac{1}{2}\cos 2x\right) = -\tfrac{1}{2}\,d\cos(2x)$$
$$= +\tfrac{1}{2}\sin(2x)\,d(2x) = \sin 2x\,dx.$$

METHOD 2. *Trigonometric Transformation and Substitution.*

$$\int \sin 2x\,dx = \int 2\sin x\cos x\,dx = -2\int \cos x\,d(\cos x)$$
$$= -(\cos x)^2 + K = -\cos^2 x + K.$$

Notice that $\cos^2 x + K = (1/2) \cos 2x + C'$ since $\cos 2x = 2 \cos^2 x - 1$. Do not be discouraged if an answer obtained seems different from an answer given in some table or book; two apparently quite different answers both may be correct, as in this example, for they may differ only by some constant.*

Whenever a prominent part of an integral is *accompanied by its derivative* as a coefficient of dx, *there is a strong indication of a* ***desirable substitution;*** thus if $\sin x$ occurs prominently and is accompanied by $\cos x\, dx$, substitute $u = \sin x$; if $\log x$ is prominent and is accompanied by $(1/x)dx$, set $u = \log x$; if any function $f(x)$ occurs prominently and is accompanied by $df(x)$, set $u = f(x)$. This is further illustrated in exercises below.

98. Substitutions in Definite Integrals. In evaluating definite integrals, the new letter introduced by a substitution may either be replaced by the original one after integration, or the values of the new letter which correspond to the given limits of integration may be substituted directly without returning to the original letter.

EXAMPLE 1. Compute $\displaystyle\int_{x=0}^{x=\pi/2} \sin x \cos x\, dx$.

METHOD 1. Let $u = \sin x$.

$$\int_{x=0}^{x=\pi/2} \sin x \cos x\, dx = \int_{x=0}^{x=\pi/2} u\, du$$

$$= \frac{u^2}{2}\bigg]_{x=0}^{x=\pi/2} = \frac{\sin^2 x}{2}\bigg]_{x=0}^{x=\pi/2} = \frac{1}{2}.$$

METHOD 2.

$$\int_{x=0}^{x=\pi/2} \sin x \cos x\, dx = \int_{u=0}^{u=1} u\, du = \frac{u^2}{2}\bigg]_{u=0}^{u=1} = \frac{1}{2},$$

since $u\ (= \sin x) = 0$ when $x = 0$, and $u = 1$ when $x = \pi/2$.

Care must be exercised to avoid errors when double-valued functions occur. The best precaution is to sketch a figure showing the relation between the old letter and the new one. In case there seems to be any doubt, it is safer to return to the original letter.

* Occasionally it is really difficult to show that two answers do actually differ by a constant in any other way than to show that the work in each case is correct and then appeal to the fundamental theorem (§ 52).

EXERCISES

Integrate each of the following expressions:

1. $\displaystyle\int (1-x)(1+x^2)\,dx.$

2. $\displaystyle\int \frac{1+2x+3x^2}{x^3}\,dx.$

3. $\displaystyle\int (a+bx)^2\,dx.$

4. $\displaystyle\int \frac{(3x-2)^2}{x^2}\,dx.$

5. $\displaystyle\int (e^x-e^{-x})^2\,dx.$

6. $\displaystyle\int \frac{x^{3/2}-4x^{2/3}}{x}\,dx.$

7. $\displaystyle\int (1-2x)^2\sqrt{x}\,dx.$

8. $\displaystyle\int (x^3-2)\,(x^{1/2}+x^{2/3})\,dx.$

In the following integrals, carry out the indicated substitution; in answers, the arbitrary constant is here omitted for convenience in printing.

9. $\displaystyle\int \sqrt{3x+2}\,dx$; set $u=3x+2$. *Ans.* $\frac{2}{9}u^{3/2}=\frac{2}{9}(3x+2)^{3/2}.$

10. $\displaystyle\int \frac{dx}{3x+2}=\tfrac{1}{3}\log(3x+2)=\log\sqrt[3]{3x+2}.$

11. $\displaystyle\int \frac{dx}{1+(3x+2)^2}=\tfrac{1}{3}\tan^{-1}(3x+2).$

12. $\displaystyle\int x\sqrt{4+x^2}\,dx$; set $u=4+x^2$. *Ans.* $u^{3/2}/3=(4+x^2)^{3/2}/3.$

13. $\displaystyle\int \frac{x\,dx}{4+x^2}=\tfrac{1}{2}\log(4+x^2)=\log\sqrt{4+x^2}.$

14. $\displaystyle\int \sin x\sqrt{\cos x}\,dx$; set $u=\cos x$. *Ans.* $-2u^{3/2}/3=-2(\cos^{3/2}x)/3.$

15. $\displaystyle\int \cos x\sqrt{\sin x}\,dx=2(\sin^{3/2}x)/3.$

16. $\displaystyle\int \cos x\,(1+4\sin x+9\sin^2 x)\,dx=\sin x+2\sin^2 x+3\sin^3 x.$

17. $\displaystyle\int \sin^3 x\,dx=\int \sin x(1-\cos^2 x)dx=-\cos x+(\cos^3 x)/3.$

18. $\displaystyle\int \cos(3x-2)\sin(3x-2)\,dx=\tfrac{1}{6}\sin^2(3x-2).$

19. $\displaystyle\int \sin(1-3x)\cos^{5/2}(1-3x)\,dx=\tfrac{2}{21}\cos^{7/2}(1-3x).$

20. $\displaystyle\int \frac{dx}{a^2+x^2}$; set $u=\dfrac{x}{a}$. *Ans.* $\dfrac{1}{a}\tan^{-1}u=\dfrac{1}{a}\tan^{-1}\dfrac{x}{a}.$

In the following integrals, find a substitution by inspection and complete the integration.

21. $\int \frac{dx}{4x+3} = \frac{1}{4} \log(4x+3) = \log(4x+3)^{1/4}$.

22. $\int \sqrt{3-4x}\, dx = -(3-4x)^{3/2}/6$.

23. $\int \sin(4x-3)\, dx = -\frac{1}{4}\cos(4x-3)$.

24. $\int \frac{2x\, dx}{2x^2-5} = \log \sqrt{2x^2-5}$.

25. $\int \cos^3 x\, dx = \sin x - (\sin^3 x)/3$. (See Ex. 17.)

26. $\int \cos x \sin^4 x\, dx = (\sin^5 x)/5$.

27. $\int 2x \cos(1+x^2)\, dx = \sin(1+x^2)$.

28. $\int \tan^3 x \sec^2 x\, dx = (\tan^4 x)/4$. $(u = \tan x.)$

29. $\int \operatorname{ctn}^3 x \csc^2 x\, dx = -(\operatorname{ctn}^4 x)/4$. $(u = \operatorname{ctn} x.)$

30. $\int \cos^2 x\, dx = \int [(1+\cos 2x)/2]\, dx = x/2 + (\sin 2x)/4$.

31. $\int \sin^2 x\, dx = \int [(1-\cos 2x)/2]\, dx = x/2 - (\sin 2x)/4$.

32. $\int \cos^5 x\, dx = \sin x - 2(\sin^3 x)/3 + (\sin^5 x)/5$.

33. $\int \operatorname{ctn} x\, dx = \int (\cos x/\sin x)\, dx = \log \sin x$. (Put $u = \sin x$).

34. $\int \tan x\, dx = -\log \cos x = \log \sec x$.

35. $\int \frac{dx}{\sqrt{4-x^2}} = \sin^{-1}\left(\frac{x}{2}\right)$.

36. $\int \frac{dx}{6+3x^2} = \frac{1}{3}\int \frac{dx}{2+x^2} = \frac{1}{3\sqrt{2}} \tan^{-1}\left(\frac{x}{\sqrt{2}}\right)$.

37. $\int \frac{dx}{\sqrt{12-4x^2}} = \frac{1}{2}\int \frac{dx}{\sqrt{3-x^2}} = \frac{1}{2}\sin^{-1}\left(\frac{x}{\sqrt{3}}\right)$.

Compute the values of each of the following definite integrals.

38. $\displaystyle\int_{x=0}^{x=1} \frac{dx}{3+x^2} = \frac{1}{\sqrt{3}} \tan^{-1} \frac{x}{\sqrt{3}}\Big]_{x=0}^{x=1} = \frac{1}{\sqrt{3}} \tan^{-1} \frac{1}{\sqrt{3}} = \frac{\pi}{6\sqrt{3}}.$

39. $\displaystyle\int_{x=0}^{x=\sqrt{3}} \frac{dx}{\sqrt{3-x^2}} = \sin^{-1}\left(\frac{x}{\sqrt{3}}\right)\Big]_{x=0}^{x=\sqrt{3}} = \sin^{-1} 1 = \frac{\pi}{2}.$

40. $\displaystyle\int_{x=0}^{x=3} \frac{x\,dx}{3+x^2} = \tfrac{1}{2} \log_e (3+x^2)\Big]_{x=0}^{x=3} = \tfrac{1}{2}(\log_e 12 - \log_e 3) = \log_e 2.$

41. $\displaystyle\int_{x=0}^{x=1} \frac{x\,dx}{\sqrt{2-x^2}} = -\sqrt{2-x^2}\Big]_{x=0}^{x=1} = -(\sqrt{1}-\sqrt{2}) = .4142+.$

42. $\displaystyle\int_{x=0}^{x=\pi/2} \sin^3 x\,dx = \Big[-\cos x + (\cos^3 x)/3\Big]_{x=0}^{x=\pi/2} = 2/3.$

43. $\displaystyle\int_{x=0}^{x=1} x\,e^{x^2}\,dx = e^{x^2}/2\Big]_{x=0}^{x=1} = e/2 - 1/2 = .8591+.$

44. $\displaystyle\int_{x=-1}^{x=2} \sqrt{2+x}\,dx.$

45. $\displaystyle\int_{x=1}^{x=2} e^{-2x}\,dx.$

46. $\displaystyle\int_{x=0}^{x=\pi/3} \sin^4 x \cos x\,dx.$

47. $\displaystyle\int_{x=0}^{x=\pi/6} \sin 3x\,dx.$

48. $\displaystyle\int_{x=0}^{x=1} \frac{dx}{6+2x^2}.$

49. $\displaystyle\int_{x=1}^{x=2} \frac{1+2x}{x+x^2}\,dx.$

50. $\displaystyle\int_{x=0}^{x=\pi/4} \cos^2 x\,dx.$

51. $\displaystyle\int_{x=0}^{x=\pi/4} \cos^3 x\,dx.$

52. Find the area under the witch $y = 1/(a+bx^2)$ for $a = 9$, $b = 1$, from $x = 0$ to $x = 1$; for $a = 8$, $b = 2$, from $x = 1$ to $x = 10$. See *Tables*, III, J.

53. Find the volume of the solid of revolution formed by revolving one arch of the curve $y = \sin x$ about the x-axis.

54. Find the area under the general catenary

$$y = a \cosh (x/a) = a(e^{x/a} + e^{-x/a})/2$$

from $x = 0$ to $x = a$.

55. Find the area of one arch of the cycloid

$$x = a\,(\theta - \sin\theta),\ y = a\,(1 - \cos\theta).$$

56. Find the volume of the solid of revolution formed by revolving one arch of the cycloid about the x-axis.

57. Compare the area of one arch of the curve $y = \sin x$ with that of one arch of the curve $y = \sin 2x$; with that of one arch of $y = \sin^2 x$.

58. Show how any odd power of $\sin x$ or of $\cos x$ can be integrated by the device used in Ex. 17.

59. Show how any power of $\sin x$ multiplied by an odd power of $\cos x$ can be integrated.

99. Integration by Parts. Use of Rule [VI]. — One of the most useful formulas in the reduction of an integral to a known form is [VI], which we here rewrite in the form

$$\text{[VI']} \qquad \int u\,dv = uv - \int v\,du$$

called the formula for ***integration by parts.*** Its use is illustrated sufficiently by the following examples:

EXAMPLE 1. $\int x \sin x\,dx$. Put $u = x$, $dv = \sin x\,dx$; then $du = dx$ and $v = \int \sin x\,dx = -\cos x$; hence,

$$\int x \sin x\,dx = -x\cos x + \int \cos x\,dx = -x\cos x + \sin x; \text{ (check)}.$$

EXAMPLE 2. $\int \log x\,dx$. Put $\log x = u$, $dx = dv$; then $du = (1/x)\,dx$, $v = x$, and

$$\int \log x\,dx = x\log x - \int x\cdot\frac{1}{x}\cdot dx = x\log x - \int dx$$

$$= x\log x - x + C; \text{ (check)}.$$

EXAMPLE 3. $\int \sqrt{a^2 - x^2}\,dx$. Put $u = \sqrt{a^2 - x^2}$, $dv = dx$; then $v = x$,

$$du = \frac{-x}{\sqrt{a^2-x^2}}\,dx, \text{ and} \int \sqrt{a^2-x^2}\,dx = x\sqrt{a^2-x^2} + \int \frac{x^2\,dx}{\sqrt{a^2-x^2}};$$

but, by Algebra, $\displaystyle\int \frac{x^2\,dx}{\sqrt{a^2-x^2}} = -\int \sqrt{a^2-x^2}\,dx + \int \frac{a^2\,dx}{\sqrt{a^2-x^2}}$;

hence

$$2\int \sqrt{a^2-x^2}\,dx = x\sqrt{a^2-x^2} + \int \frac{a^2\,dx}{\sqrt{a^2-x^2}}$$

$$= x\sqrt{a^2-x^2} + a^2\sin^{-1}\left(\frac{x}{a}\right) + C.$$

This important integral gives, for example, the area of the circle $x^2 + y^2 = a^2$, since one fourth of that area is

$$\int_{x=0}^{x=a} \sqrt{a^2-x^2}\,dx = \frac{1}{2}\left[x\sqrt{a^2-x^2} + a^2\sin^{-1}\left(\frac{x}{a}\right)\right]_{x=0}^{x=a}$$

$$= \frac{1}{2}\left[a^2\cdot\frac{\pi}{2}\right] = \frac{\pi a^2}{4}.$$

EXERCISES

Carry out each of the following integrations:

1. $\int x \cos x \, dx = x \sin x + \cos x + C.$

2. $\int xe^x \, dx = e^x (x - 1) + C.$ [HINT. $u = x$, $dv = e^x \, dx$.]

3. $\int x \log x \, dx = - x^2/4 + (x^2 \log x)/2 + C.$

4. $\int x^3 \log x \, dx = - x^4/16 + (x^4 \log x)/4 + C.$

5. $\int x^2 e^x \, dx = e^x (x^2 - 2x + 2) + C.$ [HINT. Use [VI] twice.]

6. $\int \sin^{-1} x \, dx = x \sin^{-1} x + \sqrt{1 - x^2} + C.$ [HINT. $u = \sin^{-1} x$.]

7. $\int \tan^{-1} x \, dx = x \tan^{-1} x - \log (1 + x^2)^{1/2} + C.$

8. $\int x^2 \tan^{-1} x \, dx = (x^3 \tan^{-1} x)/3 - x^2/6 + \log (1 + x^2)^{1/6} + C.$

9. $\int x (e^x - e^{-x})/2 \, dx = \int x \sinh x \, dx = x \cosh x - \sinh x + C.$

10. $\int x^2 e^{3x} \, dx = e^{3x} (9x^2 - 6x + 2)/27 + C.$

11. $\int e^x \sin x \, dx = e^x (\sin x - \cos x)/2.$ [Set $u = e^x$; use [VI] twice.]

12. $\int e^{2x} \cos 3x \, dx = e^{2x} (3 \sin 3x + 2 \cos 3x)/13.$

13. $\int e^{-x} \sin 3x \, dx = - e^{-x} (3 \cos 3x + \sin 3x)/10.$

14. $\int e^{ax} \cos nx \, dx = e^{ax} (n \sin nx + a \cos nx)/(a^2 + n^2).$

15. Show that $\int P(x) \tan^{-1} x \, dx$, where $P(x)$ is any polynomial, reduces to an algebraic integral by means of [VI]. Show how to integrate the remaining integral.

16. Show that $\int P(x) \log x \, dx$, where $P(x)$ is any polynomial, reduces to an algebraic integral by means of [VI]. Show how to integrate the remaining integral.

17. Express $\int x^n e^{ax} \, dx$ in terms of $\int x^{n-1} e^{ax} \, dx$. Hence show that $\int P(x) e^{ax} \, dx$ can be integrated, where $P(x)$ is any polynomial.

Carry out each of the following integrations:

18. $\int (2 - 4x + 3x^2) \log x \, dx$.

19. $\int (3x^2 + 4x + 1) \tan^{-1} x \, dx$.

20. $\int (x^2 - x)e^{-2x} \, dx$.

21. $\int (x^3 - 5)e^{4x} \, dx$.

22. From the rule for the derivative of a quotient, derive the formula $\int (1/v)du = u/v + \int (u/v^2) \, dv$. Show that this rule is equivalent to [VI] if u and v in [VI] are replaced by $1/v$ and u, respectively.

23. Integrate $\int e^x \sin x \, dx$ by applying [VI] once with $u = e^x$, then with $u = \sin x$, and adding.

24. Integrate $\int e^{ax} \sin nx \, dx$ by the scheme of Ex. 23.

Find the values of each of the following definite integrals:

25. $\int_{x=1}^{x=e} \log x \, dx$.

26. $\int_{x=-1}^{x=2} xe^{-x} \, dx$.

27. $\int_{x=0}^{x=1/2} \sin^{-1} x \, dx$.

28. $\int_{x=0}^{x=1} (1 + 3x^2) \tan^{-1} x \, dx$.

29. $\int_{x=0}^{x=\pi/2} e^{-2x} \cos 3x \, dx$.

30. $\int_{x=1}^{x=2} (e^x - e^{-x}) \, dx$.

31. Find the area under the curve $y = e^{-x} \sin x$ from $x = 0$ to $x = \pi$.

Find the area under each of the following curves, from $x = 0$ to $x = 1$.

32. $y = xe^{-x}$. **33.** $y = x^2 e^{-x}$. **34.** $y = x^3 e^{-x}$.

35. Compare the area beneath the curve $y = \log x$ from $x = 1$ to $x = e$ with the area between this curve and the y-axis, and the lines $y = 0$ and $y = 1$.

36. Show that the sum of the area beneath the curve $y = \sin x$ from $x = 0$ to $x = k$ and that beneath the curve $y = \sin^{-1} x$ from $x = 0$ to $x = \sin k$ is the area of a rectangle whose diagonal joins (0,0) and $(k, \sin k)$.

100. Rational Fractions. Method of Partial Fractions. A fraction N/D, whose numerator and denominator are polynomials, is called a rational fraction. If such a rational fraction is to be integrated, we first note whether or not the degree of N is less than the degree of D. If not, we divide

N by D, to obtain a quotient Q and a remainder R whose degree is less than that of D.

EXAMPLE. $\dfrac{N}{D} = \dfrac{2x^4 + x^2 + 2x - 1}{x^3 + x} = 2x + \dfrac{2x - 1 - x^2}{x^3 + x}.$

The integration of Q can be carried out at once. It remains only to consider the integration of rational fractions of the form R/D, where the degree of R is less than that of D. We shall proceed to discuss the integration of such forms, and we shall divide the discussion into several cases.

101. Case I. Denominator Linear or a Power of a Linear Form. If the denominator of the fraction R/D (§ 100) is linear, or is a power of a linear form, *i.e.* if

$$D = ax + b, \quad \text{or} \quad D = (ax + b)^n,$$

the substitution $u = ax + b$ transforms the integral of R/D into a new form which is readily integrated. For this reason, we shall reduce other cases to this case whenever possible.

102. Case II. Denominator the Product of Several Linear Factors. If the denominator of the fraction R/D (§ 100) is the product of several linear factors, the fractions R/D may be replaced by a sum of simpler fractions. The simpler fractions which compose this sum are called ***partial fractions***. Each linear factor $ax + b$ of D gives rise to one such partial fraction, whose denominator is $ax + b$ and whose numerator is a constant. Each of these partial fractions can be integrated as in § 101. The process is illustrated by the following example.

EXAMPLE. Evaluate the integral $\displaystyle\int \frac{6x^2 + 3x - 15}{(x-1)(x+1)(x+2)}\,dx.$

The numerator of the integrand is already of less degree than the denominator. We first set down the partial fraction sum just described:

$$\frac{6x^2 + 3x - 15}{(x-1)(x+1)(x+2)} = \frac{A}{x-1} + \frac{B}{x+1} + \frac{C}{x+2},$$

where the constants A, B, C are as yet unknown. To find them, we clear of fractions, obtaining the equation

$$6x^2 + 3x - 15 = A(x+1)(x+2) + B(x-1)(x+2) + C(x-1)(x+1),$$

which must hold for every value of x. If any three values of x are substituted for x in turn, we obtain three equations that may be solved for A, B, and C. Values that are particularly simple are $x = 1$, $x = -1$, and $x = -2$. Substituting each of these in turn, we get $A = -1$, $B = 6$, $C = 1$. It follows that we may write

$$\frac{6x^2 + 3x - 15}{(x-1)(x+1)(x+2)} = -\frac{1}{x-1} + \frac{6}{x+1} + \frac{1}{x+2}.$$

Each of the fractions on the right may be integrated readily as in § 101. Hence

$$\begin{aligned}\int \frac{6x^2 + 3x - 15}{(x-1)(x+1)(x+2)}\,dx &= \int \frac{-1}{x-1}\,dx + \int \frac{6}{x+1}\,dx + \int \frac{1}{x+2}\,dx \\ &= -\log(x-1) + 6\log(x+1) + \log(x+2) \\ &= \log \frac{(x+1)^6 (x+2)}{x-1}.\end{aligned}$$

103. Case III. Repeated Linear Factors. If one of the linear factors of the denominator D (§ 100) is repeated, *i.e.*, if there is a factor of D of the form $(ax+b)^n$, that factor gives rise to several partial fractions of the form

$$\frac{A}{ax+b} + \frac{B}{(ax+b)^2} + \frac{C}{(ax+b)^3} + \cdots + \frac{L}{(ax+b)^n}.$$

Otherwise the process remains as in § 102. This case is illustrated by the following example.

EXAMPLE. Evaluate the integral $\displaystyle\int \frac{3x^2 - x + 1}{(x+2)(x-2)^3}\,dx.$

According to the processes described in §§ 102-103, we first write

$$\frac{3x^2 - x + 1}{(x+2)(x-3)^3} = \frac{A}{x+2} + \frac{B}{x-3} + \frac{C}{(x-3)^2} + \frac{D}{(x-3)^3}.$$

To find A, B, C, and D, we clear of fractions

$$\begin{aligned}3x^2 - x + 1 = A(x-3)^3 + B(x+2)(x-3)^2 + C(x+2)(x-3) \\ + D(x+2)\end{aligned}$$

and then substitute for x, in turn, any four values of x. If we take $x = -2, 0, 1$, and 3, in turn, we find $A = -3/25$, $B = 3/25$, $C = 12/5$, $D = 5$. Hence

$$\int \frac{3x^2 - x + 1}{(x+2)(x-3)^3}\,dx$$
$$= \int \frac{-3\,dx}{25(x+2)} + \int \frac{3\,dx}{25(x-3)} + \int \frac{12\,dx}{5(x-3)^2} + \int \frac{5\,dx}{(x-3)^3}$$
$$= -\frac{3}{25}\log(x+2) + \frac{3}{25}\log(x-3) - \frac{12}{5(x-3)} - \frac{5}{2(x-3)^2}$$
$$= \frac{3}{25}\log\frac{x-3}{x+2} - \frac{24x - 47}{10(x-3)^2}.$$

104. Case IV. Quadratic Factors. If the denominator D (§ 100) contains a quadratic factor $ax^2 + bx + c$ which cannot be factored into real linear factors, we insert in the sum of partial fractions one fraction whose denominator is that quadratic factor and whose numerator is a linear expression $Ax + B$. The resulting fraction

$$\frac{Ax + B}{ax^2 + bx + c}$$

can always be integrated. The process is illustrated in the example which follows, and in exercises in the following list. The general case is treated in the *Tables*, IV, B, No. 21, p. 38.

EXAMPLE. Evaluate the integral $\int \frac{10x - 5}{(x-1)(x^2+4)}\,dx$.

We first write

$$\frac{10x - 5}{(x-1)(x^2+4)} = \frac{A}{x-1} + \frac{Bx + C}{x^2+4}.$$

Clearing of fractions, we have

$$10x - 5 = A(x^2 + 4) + (x - 1)(Bx + C).$$

Setting $x = 1, 0, -1$, in turn, we find $A = 1$, $B = -1$, $C = 9$. Hence

$$\int \frac{10x - 5}{(x-1)(x^2+4)}\,dx = \int \frac{dx}{x-1} - \int \frac{x-9}{x^2+4}\,dx.$$

The first integral on the right is easily evaluated by § 101. The second integral on the right may be broken up into two parts which can be integrated separately:

$$\int \frac{x-9}{x^2+4}\,dx = \int \frac{x}{x^2+4}\,dx - 9\int \frac{dx}{x^2+4}$$

$$\int \frac{x}{x^2+4}\,dx = \frac{1}{2}\log(x^2+4) \qquad \text{(See Ex. 13, p. 160.)}$$

$$\int \frac{dx}{x^2+4}\,dx = \frac{1}{2}\tan^{-1}\frac{x}{2} \qquad \text{(See Ex. 20, p. 160.)}$$

Collecting all these partial results, we have

$$\int \frac{10x-5}{(x-1)(x^2+4)}\,dx = \log(x-1) - \left\{\frac{1}{2}\log(x^2+4) - \frac{9}{2}\tan^{-1}\frac{x}{2}\right\}$$

$$= \log\frac{x-1}{\sqrt{x^2+4}} + \frac{9}{2}\tan^{-1}\frac{x}{2}.$$

105. Case V. Repeated Quadratic Factors. If the denominator D (§ 100) contains a quadratic factor to a power, *i.e.*, if D has a factor of the form $(ax^2+bx+c)^n$, we insert among the partial fractions a set of fractions analogous to those of § 103, but with numerators that are linear, and with denominators that are successive powers of the quadratic:

$$\frac{Ax+B}{ax^2+bx+c} + \frac{Bx+D}{(ax^2+bx+c)^2} + \cdots + \frac{Lx+M}{(ax^2+bx+c)^n}.$$

The determination of the unknown constants A, B, C, etc., is performed as before. In general, the resulting partial fractions can always be integrated, but the problems become more and more difficult as the exponent n increases. The method of integration essentially depends on the process of § 99 (*integration by parts*). Difficult examples should not be attempted without the assistance of the Tables, where the results of integration by parts are given in the general formulas 23 and 25, p. 38.* These, together with formulas

* Even when it is desired to proceed without the use of tables, it is best, for difficult examples, to derive such formulas as 23 and 25, p. 38 (Tables), once for all, by integration by parts, and then to use these formulas instead of repeating the work in each example.

21, 22, and 24, p. 38, are sufficient to integrate any such expression. The process is illustrated by the following example.

EXAMPLE. Evaluate the integral $\int \frac{10x^3 + 7x + 4}{(x-2)(x^2+3)^2}dx.$

As indicated above, we first set

$$\frac{10x^3 + 7x + 4}{(x-2)(x^2+3)^2} = \frac{A}{x-2} + \frac{Bx + C}{x^2+3} + \frac{Dx + E}{(x^2+3)^2}$$

Clearing of fractions and determining the constants as before, we find $A = 2$, $B = -2$, $C = 6$, $D = 6$, and $E = -11$. It follows that

$$\int \frac{10x^3 + 7x + 4}{(x-2)(x^2+3)^2}dx = \int \frac{2}{x-2}dx + \int \frac{-2x+6}{x^2+3}dx + \int \frac{6x - 11}{(x^2+3)^2}dx.$$

The first integral on the right can be evaluated by § 101. The second one can be evaluated as shown in the example of § 104. The last integral may be evaluated either by an integration by parts, or by use of the formulas 22 and 23 on p. 38 of the Tables.

EXERCISES

Carry out each of the following integrations.

1. $\int \frac{dx}{3x+5} = \log \sqrt[3]{3x+5}.$

2. $\int \frac{dx}{x^2-1} = \frac{1}{2}\int \left(\frac{1}{x-1} - \frac{1}{x+1}\right)dx = \frac{1}{2}\log\frac{x-1}{x+1}.$

3. $\int \frac{dx}{a^2-x^2} = \frac{1}{2a}\log\frac{x+a}{x-a}.$

4. $\int \frac{dx}{x^2+2x+10} = \int \frac{dx}{(x+1)^2+9} = \frac{1}{3}\tan^{-1}\frac{x+1}{3}.$

5. $\int \frac{dx}{x^2+6x+10} = \tan^{-1}(x+3).$

6. $\int \frac{dx}{4x^2+4x+2} = [\tan^{-1}(2x+1)]/2.$

7. $\int \frac{dx}{x^2+2x-3} = \int \frac{dx}{(x+1)^2-4} = \frac{1}{4}\log\frac{x-1}{x+3}.$

8. $\int \frac{dx}{4x^2+4x-8} = \frac{1}{12}\log\frac{2x-2}{2x+4} = \frac{1}{12}\log\frac{x-1}{x+2}.$

In each of the following integrals, first prepare the integrand for integration as in §§ 101–105; then complete the integrations.

9. $\int \frac{3x-7}{x^2-5x+6}dx = \log(x-2)+2\log(x-3) = \log[(x-2)(x-3)^2]$.

10. $\int \frac{4x+15}{5x+3x^2}dx = 3\log x - \frac{5}{3}\log(3x+5)$.

11. $\int \frac{x^2+2}{x^2+1}dx = x + \tan^{-1}x$.

12. $\int \frac{x-1}{x^2+2x+2}dx = \log\sqrt{x^2+2x+2} - 2\tan^{-1}(1+x)$.

13. $\int \frac{dx}{x^4+7x^2+12} = \frac{1}{\sqrt{3}}\tan^{-1}\frac{x}{\sqrt{3}} - \frac{1}{2}\tan^{-1}\frac{x}{2}$.

14. $\int \frac{4-x}{x^2-2x}dx$.

15. $\int \frac{x\,dx}{x^2+3x+2}$.

16. $\int \frac{x\,dx}{x^2-5x+6}$.

17. $\int \frac{x^2\,dx}{x^2-4}$.

18. $\int \frac{dx}{x^3+x}$.

19. $\int \frac{dx}{x^3-7x+6}$.

20. $\int \frac{dx}{x^3+2x^2}$.

21. $\int \frac{dx}{2x^3+7x^2+6x}$.

22. $\int \frac{dx}{(x-1)^2(x-2)}$.

23. $\int \frac{dx}{(x-1)(x^2+1)}$.

24. $\int \frac{x\,dx}{(x+2)(x+3)^2}$.

25. $\int \frac{2x^2+1}{x+x^3}dx$.

26. $\int \frac{x^2-5x+3}{(x+1)(x-2)^2}dx$.

27. $\int \frac{x^2\,dx}{x^4-16}$.

28. $\int \frac{x^2\,dx}{(x^2-9)^2}$.

29. $\int \frac{x^2-x+2}{x^4-5x^2+4}dx$.

Derive each of the following formulas.

30. $\int \frac{dx}{(ax+b)(mx+n)} = \frac{-1}{an-bm}\log\frac{mx+n}{ax+b}$.

31. $\int \frac{x\,dx}{(x+a)(x+b)} = \frac{1}{a-b}\log\frac{(x+a)^a}{(x+b)^b}$.

32. $\int \frac{x\,dx}{(x^2+a)(x+b)} = \frac{b}{a+b^2}\log\frac{\sqrt{x^2+a}}{x+b} + \frac{\sqrt{a}}{a+b^2}\tan^{-1}\frac{x}{\sqrt{a}}$.

33. Derive each of the formulas Nos. 18–24, *Tables*, IV, A.

Evaluate each of the following definite integrals.

34. $\displaystyle\int_{x=1}^{x=2}\frac{8-3x-x^2}{x(x+2)^2}\,dx.$ **35.** $\displaystyle\int_{x=2}^{x=4}\frac{15-7x+3x^2-3x^3}{x^4+5x^3}\,dx.$

36. $\displaystyle\int_{x=3}^{x=12}\frac{x(x-4)}{(x-2)^3}\,dx.$

[NOTE. Further practice in definite integration may be had by inserting various limits in the previous exercises.]

Carry out each of the following integrations after reducing them to algebraic form by a proper substitution.

37. $\displaystyle\int\frac{\sin x}{1+\cos^2 x}\,dx.$ **38.** $\displaystyle\int\frac{\cos x}{4-\sin^2 x}\,dx.$ **39.** $\displaystyle\int\frac{e^x\,dx}{1-e^{2x}}.$

40. $\displaystyle\int\sec x\,dx=\int\frac{\cos x}{1-\sin^2 x}dx=\frac{1}{2}\log\frac{1+\sin x}{1-\sin x}=\log\tan\left(\frac{\pi}{4}+\frac{x}{2}\right).$

41. $\displaystyle\int\csc x\,dx.$ **42.** $\displaystyle\int\operatorname{sech} x\,dx.$ **43.** $\displaystyle\int\operatorname{csch} x\,dx.$

44. $\displaystyle\int\frac{\sec^2 x}{\tan x-\tan^2 x}\,dx.$ **45.** $\displaystyle\int\frac{e^x-e^{-x}}{e^x+e^{-x}}\,dx.$

106. Rationalization of Linear Radicals. If the integrand is rational except for a radical of the form $\sqrt{ax+b}$, the substitution of a new letter for the radical

$$r=\sqrt{ax+b}$$

renders the new integrand rational.

EXAMPLE. Find $\displaystyle\int\frac{x+\sqrt{x+2}}{1+x}\,dx.$

Setting $r=\sqrt{x+2}$, we have $x=r^2-2$ and $dx=2\,r\,dr$; hence

$$\begin{aligned}\int\frac{x+\sqrt{x+2}}{1+x}\,dx&=\int\frac{r^2+r-2}{r^2-1}\,2\,r\,dr=2\int\frac{r+2}{r+1}\,r\,dr\\&=2\int\left(r+1-\frac{1}{r+1}\right)dr=r^2+2\,r-2\log(r+1)+C\\&=x+2+2\sqrt{x+2}-2\log(\sqrt{x+2}+1)+C.\end{aligned}$$

The same plan — *substitution of a new letter for the essential radical* — is successful in a large number of cases, including all those in which the radical is of one of the forms:

$$x^{1/n},\ (ax+b)^{1/n},\ \left(\frac{ax+b}{cx+d}\right)^{1/n},$$

where n is an integer. Integral powers of the essential radical may also occur in the integrand.

107. Quadratic Irrationals: $\sqrt{a+bx\pm x^2}$. If the integral involves a quadratic irrational, either of several methods may be successful, and at least one of the following always succeeds:

(*A*) If the quadratic $Q = a + bx \pm x^2$ can be factored into real factors, we have

$$\sqrt{Q} = \sqrt{(\alpha+x)\ (\beta\pm x)} = (\alpha+x)\sqrt{\frac{\beta\pm x}{\alpha+x}};$$

and the method of § 106 can be used. The resulting expressions are sometimes not so simple, however, as those found by one of the following processes.

(*B*) If the term in x^2 is positive, either of the substitutions

$$\sqrt{Q} = t + x, \quad \sqrt{Q} = t - x,$$

will be found advantageous. One of these substitutions may lead to simpler forms than the other in a given example.

(*C*) Completing the square under the radical sign throws the radical in the form

$$\sqrt{Q} = \sqrt{\pm k \pm (x\pm c)^2};$$

the substitution $x \pm c = y$ certainly simplifies the integral, and may throw it in a form which can be recognized instantly.

(D) After completing the square under the radical sign, the radical will take one of the forms $\sqrt{k^2 - x^2}$, $\sqrt{k^2 + x^2}$, $\sqrt{x^2 - k^2}$. Then a trigonometric substitution often leads to a simple form. Thus:

if $x = k \sin \theta$, $\sqrt{k^2 - x^2}$ becomes $k \cos \theta$;

if $x = k \tan \theta$, $\sqrt{k^2 + x^2}$ becomes $k \sec \theta$;

if $x = k \sec \theta$, $\sqrt{x^2 - k^2}$ becomes $k \tan \theta$.

EXAMPLE. Let $\sqrt{Q} = \sqrt{x^2 \pm a^2}$; show the effect of substituting $\sqrt{Q} = t - x$.

If $\sqrt{x^2 \pm a^2} = t - x$, we find

$$x = \frac{t^2 \mp a^2}{2\,t},\; dx = \frac{t^2 \pm a^2}{2\,t^2}\,dt,\; \sqrt{Q} = t - x = \frac{t^2 \pm a^2}{2\,t};$$

and the transformed integrand is surely rational. Carrying out these transformations in the simple examples which follow, we find

$$\text{(i)}\quad \int \frac{dx}{\sqrt{x^2 \pm a^2}} = \int \left(\frac{t^2 \pm a^2}{2\,t^2} \div \frac{t^2 \pm a^2}{2\,t}\right) dt = \int \frac{dt}{t} = \log t + C$$

$$= \log (x + \sqrt{Q}) + C, \quad \text{where} \quad Q = x^2 \pm a^2.$$

$$\text{(ii)}\quad \int \sqrt{x^2 \pm a^2}\,dx = \int \frac{t^2 \pm a^2}{2\,t} \cdot \frac{t^2 \pm a^2}{2\,t^2}\,dt = \int \left(\frac{t}{4} \pm \frac{a^2}{2\,t} + \frac{a^4}{4\,t^3}\right) dt$$

$$= \frac{t^4 - a^4}{8\,t^2} \pm \frac{a^2}{2} \log t = \frac{x\sqrt{Q}}{2} \pm \frac{a^2}{2} \log (x + \sqrt{Q}) + C.$$

These integrals are important and are repeated in the Table of Integrals, *Tables*, IV, C, 33, 45*a*. Many other integrals can be reduced to these two or to that of Ex. 3, p. 163, or to Rules [XVI] or [XX] by process (C) above.

EXERCISES

1. $\int x\sqrt{x - 1}\,dx = (1/15)\,(6\,x + 4)\,(x - 1)^{3/2}$.

2. $\int \frac{\sqrt{x + 1}}{x}\,dx = 2\sqrt{x + 1} + \log \frac{\sqrt{x + 1} - 1}{\sqrt{x + 1} + 1}$.

3. $\int \frac{dx}{x\sqrt{x - 1}} = 2 \tan^{-1} \sqrt{x - 1}$.

4. $\int \sqrt{\frac{1 - x}{1 + x}}\,dx = \sqrt{1 - x^2} + \sin^{-1} x$.

5. $\displaystyle\int \frac{dx}{(ax + 2b)\sqrt{ax+b}} = \frac{2}{a\sqrt{b}} \tan^{-1} \sqrt{\frac{ax+b}{b}}.$

6. $\displaystyle\int \frac{dx}{x^2\sqrt{x+1}} = -\frac{\sqrt{x+1}}{x} + \frac{1}{2}\log\frac{\sqrt{x+1}+1}{\sqrt{x+1}-1}.$

7. $\displaystyle\int (a+bx)^{3/2}\,dx = \frac{2}{5b}(a+bx)^{5/2}.$

8. $\displaystyle\int \frac{dx}{(a+bx)^{3/2}} = -\frac{2}{b\sqrt{a+bx}}.$

Carry out each of the following integrations.

9. $\displaystyle\int x\sqrt{1+x}\,dx.$

10. $\displaystyle\int \frac{dx}{(x-1)\sqrt{2-x}}.$

11. $\displaystyle\int \frac{dx}{(x-1)\sqrt{x-2}}.$

12. $\displaystyle\int \sqrt{\frac{1+x}{1-x}}\,dx.$

13. $\displaystyle\int \sqrt{\frac{1-x}{x}}\,dx.$

14. $\displaystyle\int \sqrt{\frac{x+1}{x-1}}\,dx.$

15. $\displaystyle\int \frac{\sqrt{x+4}}{x^2}\,dx.$

16. $\displaystyle\int \frac{\sqrt{x-4}}{x^2}\,dx.$

17. $\displaystyle\int x\sqrt[3]{1+x}\,dx.$

18. $\displaystyle\int x\sqrt[3]{3x+7}\,dx.$

19. $\displaystyle\int \frac{x\,dx}{\sqrt[3]{1-x}}.$

20. $\displaystyle\int \frac{x^2\,dx}{(x+1)^{2/3}}.$

21. $\displaystyle\int \frac{x^{1/4}\,dx}{1+\sqrt{x}}.$

22. $\displaystyle\int \frac{dx}{x^{1/2}+x^{1/6}}.$

23. $\displaystyle\int \frac{\sqrt{1-x}}{(1+x)^{3/2}}\,dx.$

24. $\displaystyle\int_0^{1/4} \frac{\sqrt{x}}{1-\sqrt{x}}\,dx.$

25. $\displaystyle\int_4^9 \frac{1+\sqrt{x}}{1-\sqrt{x}}\,dx.$

26. $\displaystyle\int_0^3 \frac{x\,dx}{1+\sqrt{1+x}}.$

Carry out each of the following integrations by first making an appropriate substitution.

27. $\displaystyle\int \frac{\cos x}{3-\sqrt{\sin x}}\,dx.$

28. $\displaystyle\int \frac{e^x\,dx}{1+e^{x/3}}.$

29. $\displaystyle\int \frac{\sec^2 x\,dx}{\sqrt{2+3\tan x}}.$

30. $\displaystyle\int \frac{\sin x\sqrt{\cos x}}{1-2\sqrt{\cos x}}\,dx.$

31. $\displaystyle\int \frac{1+\sqrt{\sin x}}{1-\sqrt{\sin x}}\cos x\,dx.$

32. $\displaystyle\int \frac{\sin x\,dx}{(2+3\cos x)^{3/2}}.$

Substitution of a new letter for the essential radical is immediately successful in the following integrals.

33. $\int x\sqrt{1+x^2}\,dx.$ **36.** $\int \frac{(1+x)\,dx}{\sqrt{2+2x+x^2}}.$ **39.** $\int x^2\sqrt{a+bx^3}\,dx.$

34. $\int \frac{x^3\,dx}{\sqrt{1+x^2}}.$ **37.** $\int \frac{x\,dx}{(a+bx^2)^{3/2}}.$ **40.** $\int \frac{x^5}{\sqrt{a+bx^3}}\,dx.$

35. $\int x(1+x^2)^{3/2}\,dx.$ **38.** $\int \frac{x\,dx}{(a+bx^2)^{p/q}}.$ **41.** $\int \frac{x^{n-1}\,dx}{\sqrt{a+bx^n}}.$

Carry out each of the following integrations.

42. $\int \frac{dx}{\sqrt{x^2-4}} = \log(x+\sqrt{x^2-4}).$

43. $\int \frac{dx}{x\sqrt{x^2-a^2}} = \frac{1}{a}\tan^{-1}\frac{\sqrt{x^2-a^2}}{a}.$

44. $\int \frac{dx}{(x+a)\sqrt{a^2-x^2}} = \frac{1}{a}\sqrt{\frac{a-x}{a+x}}.$

45. $\int \frac{dx}{(1+2x^2)\sqrt{1+x^2}} = \tan^{-1}\frac{x}{\sqrt{x^2+1}}.$

46. $\int \frac{x+1}{\sqrt{1-x^2}}\,dx = \sin^{-1}x - \sqrt{1-x^2}.$

47. $\int \frac{2x^2-a^2}{\sqrt{x^2-a^2}}\,dx = x\sqrt{x^2-a^2}.$

48. $\int \frac{dx}{\sqrt{4x^2+1}}.$ **49.** $\int \frac{dx}{x\sqrt{4x^2+1}}.$ **50.** $\int \frac{dx}{x^2\sqrt{4x^2+1}}.$

51. $\int \frac{\sqrt{x^2-1}}{x}\,dx.$ **52.** $\int \frac{\sqrt{4-x^2}}{x^2}\,dx.$ **53.** $\int \frac{2x^2-1}{\sqrt{1-x^2}}\,dx.$

The following integrations may be performed by the methods of § 107; note especially method (C), which consists in completing the square under the radical.

54. $\int \frac{dx}{\sqrt{x^2-x+1}} = \log(2x-1+2\sqrt{x^2-x+1}).$

55. $\int \frac{dx}{\sqrt{1-x-x^2}} = \sin^{-1}\frac{2x+1}{\sqrt{5}}.$

56. $\int \frac{dx}{\sqrt{4x-x^2}} = \sin^{-1}\frac{x-2}{2} = \text{vers}^{-1}\frac{x}{2}$ [+ const.].

57. $\displaystyle\int \frac{dx}{x\sqrt{x^2+x-1}} = \sin^{-1}\frac{x-2}{x\sqrt{5}}.$

58. $\displaystyle\int \frac{dx}{x\sqrt{7x^2+6x-1}} = \sin^{-1}\frac{3x-1}{4x}.$

59. $\displaystyle\int \frac{dx}{\sqrt{2x^2+x+1}}.$ 60. $\displaystyle\int \frac{dx}{\sqrt{1+x-2x^2}}.$ 61. $\displaystyle\int \frac{dx}{\sqrt{1-2x-x^2}}.$

62. $\displaystyle\int \frac{dx}{\sqrt{6x-x^2-5}}.$ 65. $\displaystyle\int \sqrt{1+x+x^2}\,dx.$

63. $\displaystyle\int \frac{dx}{x\sqrt{x^2+2x+3}}.$ 66. $\displaystyle\int \sqrt{3x^2+10x+9}\,dx.$

64. $\displaystyle\int \frac{dx}{(x+4)\sqrt{x^2+3x-4}}.$ 67. $\displaystyle\int x\sqrt{1+x+x^2}\,dx.$

Integrate by parts, [VI], each of the following integrals.

68. $\displaystyle\int x\sin^{-1}x\,dx.$ 71. $\displaystyle\int (3x-2)\sin^{-1}x\,dx.$

69. $\displaystyle\int \frac{\sin^{-1}x}{x^2}\,dx.$ 72. $\displaystyle\int \frac{2+x^2}{x^2}\cos^{-1}x\,dx.$

70. $\displaystyle\int x\cos^{-1}x\,dx.$ 73. $\displaystyle\int (\sin^{-1}x + 2x\cos^{-1}x)\,dx.$

108. Trigonometric Integrals. A number of trigonometric integrals have been evaluated in the preceding lists of exercises. The processes explained in Exs. 14, 15, 17, 25, 26, 28, 29, 30, 31, pp. 160–61, may be generalized and stated in the form of standard processes. They depend chiefly upon the use of well known relations between the trigonometric functions. (See *Tables*, pp. 12–13.)

Since it is desirable to avoid the introduction of radicals that were not present in the original example, we do not ordinarily use the trigonometric formulas that involve a square root. But it is desirable to notice that

(*a*) Any even power of $\sin x$ can be changed into a sum of powers of $\cos x$ by the relation $\sin^2 x + \cos^2 x = 1$.

(*b*) Any even power of $\cos x$ can be changed into a sum of powers of $\sin x$ by the same relation.

(*c*) Similarly, sums of even powers of $\tan x$ may be changed into sums of even powers of $\sec x$, and conversely, by the relation $\sec^2 x = 1 + \tan^2 x$.

(*d*) All the trigonometric functions may be changed into forms in $\sin x$ and $\cos x$ without introducing any new radicals.

(*e*) The square of $\sin x$ and the square of $\cos x$ may be expressed in terms of the first power of $\cos 2x$ by means of the formula $\cos 2x = \cos^2 x - \sin^2 x$.

(*f*) All the trigonometric functions can be expressed rationally in terms of $\tan (x/2)$.

109. Integration of Odd Powers of sin *x* or of cos *x*. Any odd power of $\sin x$ may be integrated, as in Ex. 17, p. 160, by the substitution $u = \cos x$.

Likewise, any odd power of $\cos x$ may be integrated by means of the substitution $u = \sin x$. (See Ex. 25, p. 161.)

More generally any integral of the form

$$\int \sin^n x \cos^m x \, dx$$

can be integrated if either m or n is an odd integer. If n is odd, set $u = \cos x$; if m is odd, set $u = \sin x$. This process is illustrated by Exs. 14, 15, 16, 18, 19, p. 160; and by the following example.

Example. Evaluate the integral $\int \sin^{3/2} x \cos^3 x \, dx$.

Set $u = \sin x$; then

$$\begin{aligned}\int \sin^{3/2} x \cos^3 x \, dx &= \int \sin^{3/2} x (1 - \sin^2 x) \cos x \, dx \\ &= \int u^{3/2} (1 - u^2) \, du \\ &= \frac{2}{5} u^{5/2} - \frac{2}{9} u^{9/2} = \frac{2}{5} \sin^{5/2} x - \frac{2}{9} \sin^{9/2} x.\end{aligned}$$

110. Reduction Formulas. If the integrand is an even power of $\sin x$ (or of $\cos x$) we may use § 108 (*e*), as in Exs. 30, 31, p. 161, or we may proceed by integration by parts, as follows. Let us first write

$$\int \sin^n x\,dx = \int \sin^{n-1} x \sin x\,dx$$

and then integrate by parts (§ 99) by taking

$$u = \sin^{n-1} x, \qquad dv = \sin x\,dx,$$
$$du = (n-1)\sin^{n-2} x \cos x\,dx, \quad v = -\cos x.$$

Then we obtain

$$\int \sin^n x\,dx = -\cos x \sin^{n-1} x + (n-1)\int \sin^{n-2} x \cos^2 x\,dx.$$

Replacing $\cos^2 x$ by $1 - \sin^2 x$ in the last integral and breaking it up into two integrals, we have,

$$\int \sin^n x\,dx = -\cos x \sin^{n-1} x + (n-1)\int \sin^{n-2} x\,dx - (n-1)\int \sin^n x\,dx.$$

Transposing the last integral and dividing by n, we find the formula (*Tables*, IV, E, 57)

$$(1)\quad \int \sin^n x\,dx = -\frac{\cos x \sin^{n-1} x}{n} + \frac{n-1}{n}\int \sin^{n-2} x\,dx.$$

Repeated applications of this formula reduce the left-hand side to integrals that involve $\sin^{n-4} x$, $\sin^{n-6} x$, $\cdots$, down to $\sin x$ if n is odd, or to $\sin^0 x$ $(= 1)$ if n is even. In either case, the integration can be completed by the use of a standard formula.

In a similar manner, we obtain the formula (*Tables*, IV, E, 60)

$$(2)\quad \int \cos^n x\,dx = \frac{\sin x \cos^{n-1} x}{n} + \frac{n-1}{n}\int \cos^{n-2} x\,dx.$$

By solving these formulas for the integral on the right-hand side, we obtain

$$(3)\qquad \int \sin^{n-2} x\, dx = \frac{\cos x \sin^{n-1} x}{n-1} + \frac{n}{n-1}\int \sin^n x\, dx;$$

and

$$(4)\qquad \int \cos^{n-2} x\, dx = -\frac{\sin x \cos^{n-1} x}{n-1} + \frac{n}{n-1}\int \cos^n x\, dx.$$

These formulas *raise* the exponent in the integrand. Hence they are useful in integrating *negative* powers of $\sin x$ and $\cos x$, *i.e.* positive powers of $\csc x$ and of $\sec x$.

An analogous integration by parts leads to the formula (*Tables*, IV, E, 64)

$$(5)\qquad \int \sin^n x \cos^m x\, dx$$
$$= \frac{\sin^{n+1} x \cos^{m-1} x}{m+n} + \frac{m-1}{m+n}\int \sin^n x \cos^{m-2} x\, dx$$
$$= -\frac{\sin^{n-1} x \cos^{m+1} x}{m+n} + \frac{n-1}{m+n}\int \sin^{n-2} x \cos^m x\, dx.$$

The proof of this formula is left as an exercise for the student. If either m or n in (5) is an odd integer, the process of § 109 is usually quicker. But if both m and n are even integers, the formula (5) is very useful.

EXAMPLE 1. Evaluate $\int \cos^4 x\, dx$.

$$\int \cos^4 x\, dx = \frac{\cos^3 x \sin x}{4} + \frac{3}{4}\int \cos^2 x\, dx$$
$$= \frac{\cos^3 x \sin x}{4} + \frac{3}{4}\left[\frac{\cos x \sin x}{2} + \frac{1}{2}\int dx\right]$$
$$= \frac{\cos^3 x \sin x}{4} + \frac{3}{8}\cos x \sin x + \frac{3}{8}x.$$

If, in this example, we should follow the method suggested under (*e*) of § 108, we would write

$$\cos^4 x = (\cos^2 x)^2 = \left(\frac{1+\cos 2x}{2}\right)^2$$
$$= \frac{1}{4}(1+2\cos 2x + \cos^2 2x)$$
$$= \frac{1}{4}\left(1+2\cos 2x + \frac{1+\cos 4x}{2}\right).$$

Then

$$\int \cos^4 x\, dx = \frac{3x}{8} + \frac{\sin 2x}{4} + \frac{\sin 4x}{32}.$$

EXAMPLE 2. Evaluate $\int \sec^3 x\, dx$.

By (4), with $n = -1$, we find

$$\int \sec^3 x\, dx = \int \cos^{-3} x\, dx = -\frac{\sin x \cos^{-2} x}{-2} + \frac{-1}{-2}\int \cos^{-1} x\, dx$$
$$= \frac{\sin x \sec^2 x}{2} + \frac{1}{2}\int \sec x\, dx.$$

The integration may now be completed by means of Ex. 40, p. 172, which is essentially an application of § 109.

EXAMPLE 3. Evaluate $\int \sin^2 x \cos^4 x\, dx$.

By the second part of (5), we have

$$\int \sin^2 x \cos^4 x\, dx = -\frac{\sin x \cos^5 x}{6} + \frac{1}{6}\int \cos^4 x\, dx.$$

The example may now be completed by following Example 1.

111. Powers of tan x and of sec x. Any even power of tan x may be reduced to a sum of even powers of sec x (§ 108 (*c*)). This may be integrated by the method mentioned in § 110.

Another method of integrating any even power of sec x consists in making the substitution $u = \tan x$. Since $du = \sec^2 x\, dx$, and since even powers of sec x may be reduced to a sum of even powers of tan x (§ 108 (*c*)), the integration becomes very simple, as is illustrated by Example 1 below.

Odd powers of sec x can be most readily integrated by the method of § 110, as shown in Example 2, § 110.

Any positive integral power of tan x may be integrated by reducing it to one of the two integrals:

(1) $\int \tan x\,dx = -\log\cos x = \log\sec x$. (See Exs. 33, 34, p. 161.)

(2) $\int \tan^2 x\,dx = \int (\sec^2 x - 1)\,dx = \tan x - x,$

by means of the reduction formula (see *Tables* IV, E, 70):

(3) $$\int \tan^n x\,dx = \frac{\tan^{n-1} x}{n-1} - \int \tan^{n-2} x\,dx.$$

This reduction formula is obtained as follows:

$$\int \tan^n x\,dx = \int \tan^{n-2} x \tan^2 x\,dx = \int \tan^{n-2} x\,(\sec^2 x - 1)\,dx$$
$$= \int \tan^{n-2} x \sec^2 x\,dx - \int \tan^{n-2} x\,dx.$$

If we set $u = \tan x$ in the first integral on the right-hand side, we obtain the formula (3).

EXAMPLE 1. Evaluate the integral $\int \sec^4 x\,dx$.

Put $u = \tan x$; then $du = \sec^2 x\,dx$, and we may write

$$\int \sec^4 x\,dx = \int \sec^2 x \sec^2 x\,dx = \int (1 + \tan^2 x)\sec^2 x\,dx$$
$$= \int (1 + u^2)\,du = u + \frac{u^3}{3} = \tan x + \frac{\tan^3 x}{3}.$$

EXAMPLE 2. Evaluate $\int \tan^4 x\,dx$.

As indicated above, we may write

$$\int \tan^4 x\,dx = \int (\sec^2 x - 1)^2\,dx = \int (\sec^4 x - 2\sec^2 x + 1)\,dx$$
$$= \int \sec^4 x\,dx - 2\tan x + x.$$

The remaining integral may be integrated as in Example 1. The student should also apply the reduction formula (3) to this integral.

EXAMPLE 3. Evaluate $\int \tan^3 x\,dx$.

Applying (3) we have

$$\int \tan^3 x\,dx = \frac{\tan^2 x}{n-1} - \int \tan x\,dx = \frac{\tan^2 x}{n-1} + \log\cos x.$$

EXERCISES

Evaluate the following integrals.

1. $\int \sin^4 x\,dx.$ 2. $\int \sin^2 x \cos^2 x\,dx.$ 3. $\int \tan^6 x\,dx.$

4. $\int \tan^5 x\,dx.$ 5. $\int \sec^2 x \tan^4 x\,dx.$ 6. $\int \csc^3 x\,dx.$

7. $\int \tan x \sec^4 x\,dx.$ 8. $\int \csc^4 x\,dx.$ 9. $\int \csc^6 x\,dx.$

10. $\int \cot^4 x\,dx.$ 11. $\int \cot^5 x\,dx.$ 12. $\int \tan^2 x \csc^2 x\,dx.$

13. $\int \csc x \cot^2 x\,dx.$ 14. $\int \frac{dx}{\sin x \cos x}.$ 15. $\int \frac{dx}{\sin x \cos^3 x}.$

16. $\int \frac{dx}{\sin^2 x \cos^2 x}.$ 17. $\int \frac{\sin (x+a)}{\sin x}\,dx.$ 18. $\int \frac{dx}{\sqrt{\sin x \cos^3 x}}.$

19. $\int \sin^2 x \cos^3 x\,dx.$ 20. $\int \sin^3 x \cos^2 x\,dx.$ 21. $\int \frac{\cos^3 x}{\sin^2 x}\,dx.$

22. $\int \frac{\cos^4 x}{\sin^2 x}\,dx.$ 23. $\int \sin^3 x \cos^3 x\,dx.$ 24. $\int \frac{dx}{\sin^2 x \cos^4 x}.$

25. $\int \frac{\sin^3 x\,dx}{\cos x}.$ 26. $\int \frac{\sin^3 x}{\cos^2 x}\,dx.$ 27. $\int \frac{\cos^2 x}{\sin^3 x}\,dx.$

28. $\int \sin^4 x \cos^3 x\,dx.$ 29. $\int \sin 4x \cos 3x\,dx.$ 30. $\int \sin 3x \cos 4x\,dx.$

31. Verify formula 111 of Table IV, E.

32. Verify formula 112 of Table IV, E.

112. Elliptic and Other Integrals. If the only irrationality is $\sqrt{Q}$, where Q is a polynomial of the third or fourth degree, the integral is called an ***elliptic integral***. While no treatment of these integrals is given here, they are treated briefly in tables of integrals, and their values have been computed in the form of tables.* See *Tables*, V, D, E.

* Some idea of these quantities may be obtained by imagining some person ignorant of logarithms. Then $\int (1/x)\,dx$ would be beyond his powers, and we should tell him "*values of the integral* $\int (1/x)\,dk$ *can be found tabulated*," which is precisely what is done in tables of Napierian logarithms. Of course as little as possible is tabulated; other allied forms are reduced to those tabulated by means of special formulas, given in the tables.

The discussion of such integrals, as well as of those in which Q is of degree higher than four, is beyond the scope of this book.

113. Binomial Differentials. Among the forms which are shown in tables of integrals to be reducible to simpler ones are the so-called ***binomial differentials:***

$$\int (ax^n + b)^p x^m \, dx.$$

It is shown by integration by parts that such forms can be replaced by any one of the following combinations, where u stands for $(ax^n + b)$:

$$(1) \qquad \int u^p x^m \, dx = (A_1)\, u^p x^{m+1} \qquad + (B_1) \int u^{p-1} x^m \, dx,$$

$$(2) \qquad \int u^p x^m \, dx = (A_2)\, u^{p+1} x^{m+1} \quad + (B_2) \int u^{p+1} x^m \, dx,$$

$$(3) \qquad \int u^p x^m \, dx = (A_3)\, u^{p+1} x^{m+1} \quad + (B_3) \int u^p x^{m+n} \, dx,$$

$$(4) \qquad \int u^p x^m \, dx = (A_4)\, u^{p+1} x^{m-n+1} + (B_4) \int u^p x^{m-n} \, dx,$$

where A_1, A_2, A_3, A_4, B_1, B_2, B_3, B_4, are certain constants.

These rules may be used either by direct substitution from a table of integrals in which the values of the constants are given in general * (see *Tables*, IV, D, 51–54), or we may denote the unknown constants by letters and find their values by differentiating both sides and comparing coefficients.

* Such formulas are called *reduction formulas*; many other such formulas — notably for trigonometric functions — are given in tables of integrals. (See *Tables*, IV, E_a, 57, 60, 64, etc.) It is strongly advised that no effort be made to memorize any of these forms, — not even the skeleton forms given above. A far more profitable effort is to grasp the essential notion of the types of changes which can be made in these and other integrals, so that good judgment is formed concerning the possibility of integrating given expressions. Then the actual integration is usually performed by means of a table. See also *Tables*, IV, E_a, 78, 82 (*b*); E_b, 85, 86; E_c, 92–94; E_d, 98, 106; B, 17 (*b*), 25; etc.

EXAMPLE 1. $\int \frac{dx}{(ax^2+b)^{3/2}} = A\frac{x}{(ax^2+b)^{1/2}} + B\int \frac{dx}{(ax^2+b)^{1/2}}$, by (2).

Differentiating and comparing coefficients of x^2 and x^0, we find $B = 0$ and $A = 1/b$; hence

$$\int \frac{dx}{(ax^2+b)^{3/2}} = \frac{x}{b\sqrt{(ax^2+b)}}; \text{ (check).}$$

EXAMPLE 2. $\int \frac{x^3dx}{(ax^2+b)^{3/2}} = \frac{Ax^2}{(ax^2+b)^{1/2}} + B\int \frac{xdx}{(ax^2+b)^{3/2}}$, by (4).

Here $A = 1/a,\ B = -2\,b/a,$

and
$$\int \frac{x^3dx}{(ax^2+b)^{3/2}} = \frac{ax^2+2b}{a^2\sqrt{(ax^2+b)}}.$$

114. General Remarks. The student will see that integration is largely a trial process, the success of which is dependent upon a ready knowledge of algebraic and trigonometric transformations. Skill will come only from constant practice. A very considerable help in this practice is a table of integrals (see *Tables*, IV, A–H). The student should apply his intelligence in the use of such tables, testing the results there given, endeavoring to see how they are obtained, studying the classification of the table; in brief, *mastering* the table, not becoming a slave to it.

In the list which follows, many examples can be done by the processes mentioned above. The exercises 43–97 may be reserved for practice in using a table of integrals.

REVIEW EXERCISES

1. $\int \frac{x^2+4\,x}{(x+2)^2}\,dx.$

2. $\int \frac{2\,x^2+6\,x+15}{(2\,x+3)^2}\,dx.$

Find the values of the following definite integrals by using the tabulated numerical values: *Tables*, V, A–H:

78. $\int_{x=0}^{x=1.5} e^x\,dx.$

79. $\int_{x=1.2}^{x=2.5} e^{2x}\,dx.$

80. $\int_{x=0}^{x=1.4} e^{-x}\,dx.$

81. $\int_{x=1}^{x=2.3} \frac{1}{x}\,dx.$

82. $\int_{x=3.5}^{x=4.1} \frac{1}{x-2}\,dx.$

83. $\int_{x=2.1}^{x=3.2} \frac{1}{x^2-1}\,dx.$

84. $\int_{x=0}^{x=1.4} \frac{e^x+e^{-x}}{2}\,dx = \int_{x=0}^{x=1.4} \cosh x\,dx.$

85. $\int_{x=0}^{x=2.3} \sinh x\,dx.$

86. $\int_{x=1}^{x=2} \frac{dx}{\sqrt{x^2-1}} = \cosh^{-1} x\Big]_{x=1}^{x=2}.$

87. $\int_{x=0}^{x=1} \frac{dx}{\sqrt{x^2+1}} = \sinh^{-1} x\Big]_{x=0}^{x=1}.$

88. $\int_{x=2}^{x=3.6} \frac{dx}{\sqrt{x^2-4}} = \cosh^{-1}\frac{x}{2}\Big]_{x=2}^{x=3.6}.$

89. $\int_{x=0}^{x=14.4} \frac{dx}{\sqrt{x^2+9}} = \sinh^{-1}\frac{x}{3}\Big]_{x=0}^{x=14.4}.$

90. $\int_{\theta=0^\circ}^{\theta=30^\circ} \frac{d\theta}{\sqrt{1-(1/4)\sin^2\theta}} = F(\tfrac{1}{2}, 30^\circ)$, *Tables*, V, D.

91. $\int_{\theta=0^\circ}^{\theta=45^\circ} \sqrt{1-(1/4)\sin^2\theta}\,d\theta = E(\tfrac{1}{2}, 45^\circ)$, *Tables*, V, E.

92. $\int_{\theta=15^\circ}^{\theta=45^\circ} \frac{d\theta}{\sqrt{1-.04\sin^2\theta}}.$ **93.** $\int_{\theta=30^\circ}^{\theta=90^\circ} \sqrt{1-.25\sin^2\theta}\,d\theta.$

94. $\int_{x=0}^{x=1/2} \frac{dx}{\sqrt{1-x^2}\sqrt{1-.25x^2}} = \int_{\theta=0^\circ}^{\theta=30^\circ} \frac{d\theta}{\sqrt{1-.25\sin^2\theta}},$

if $x = \sin\theta$.

95. $\displaystyle\int_{x=1/2}^{x=1}\sqrt{\frac{1-.36\,x^2}{1-x^2}}\,dx=\int_{\theta=30°}^{\theta=90°}\sqrt{1-.36\sin^2\theta}\,d\theta$, if $x=\sin\theta$.

96. $\displaystyle\int_{x=1/2}^{x=1}\frac{dx}{\sqrt{1-x^2}\sqrt{1-.49\,x^2}}$. **97.** $\displaystyle\int_{x=\sqrt{2}/2}^{x=\sqrt{3}/2}\sqrt{\frac{1-.16\,x^2}{1-x^2}}\,dx.$

[NOTE. Many of the exercises in preceding lists may be used for additional practice in use of the tables.]

115. Limits Infinite. Horizontal Asymptote. If a curve approaches the x-axis as an asymptote, it is conceivable that the total area between the x-axis, the curve, and a left-hand vertical boundary may exist; by this total area we mean the *limit* of the area from the left-hand boundary out to any vertical line $x=m$, as m becomes infinite.

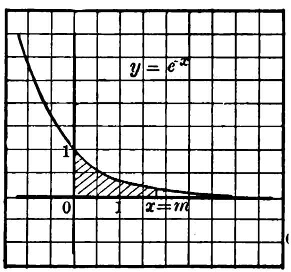

FIG. 42.

EXAMPLE 1. The area under the curve $y=e^{-x}$ from the y-axis to the ordinate $x=m$ is

$$A\Big]_{x=0}^{x=m}=\int_{x=0}^{x=m}e^{-x}\,dx=1-e^{-m}.$$

As m becomes infinite e^{-m} approaches zero; hence

$$A\Big]_{x=0}^{x=\infty}=\int_{x=0}^{x=\infty}e^{-x}\,dx=\lim_{m\to\infty}\int_{x=0}^{x=m}e^{-x}\,dx=\lim_{m\to\infty}(1-e^{-m})=1,$$

and we say that the total area under the curve $y=e^{-x}$ from $x=0$ to $x=+\infty$ is 1.

EXAMPLE 2. The area under the hyperbola $y=1/x$ from $x=1$ to $x=m$ is

$$A\Big]_{x=1}^{x=m}=\int_{x=1}^{x=m}\frac{dx}{x}=\log x\Big]_{x=1}^{x=m}=\log m.$$

As m becomes infinite, $\log m$ becomes infinite, and

$$\lim_{m\to\infty}\left\{A\Big]_{x=1}^{x=m}\right\}=\lim_{m\to\infty}\log m$$

does not exist; hence we say that the total area between the x-axis and the hyperbola from $x=1$ to $x=\infty$ *does not exist.**

*This is the standard short expression to denote what is quite obvious,—that the area up to $x=m$ becomes infinite as m becomes infinite. This result makes any consideration of the area up to $x=\infty$ perfectly useless; hence the expression "fails to exist," which is slightly more general.

116. Integrand Infinite. Vertical Asymptotes. If the function to be integrated becomes infinite, the situation is precisely similar to that of § 115; graphically, the curve whose area is represented by the integral has in this case a vertical asymptote.

If $f(x)$ becomes infinite at one of the limits of integration, $x = b$, we define the integral, as in § 115, by a limit process:

$$\int_{x=a}^{x=b} f(x)\,dx = \lim_{c\to 0} \int_a^{b-c} f(x)\,dx.$$

A similar definition applies if $f(x)$ becomes infinite at the lower limit, as in the following example.

EXAMPLE 1. The area between the curve $y = 1/\sqrt{x}$ and the two axes, from $x = 0$ to $x = 1$, is

$$A\Big]_{x=0}^{x=1} = \int_{x=0}^{x=1} \frac{1}{\sqrt{x}}\,dx = \lim_{c\to 0}\left[\int_{x=c}^{x=1} \frac{1}{\sqrt{x}}\,dx\right]$$
$$= \lim_{c\to 0}\left[2\sqrt{x}\right]_{x=c}^{x=1} = \lim_{c\to 0}\left[2 - 2\sqrt{c}\right] = 2.$$

EXAMPLE 2. The area between the hyperbola $y = 1/x$, the vertical line $x = 1$, and the two axes, *does not exist.* For,

$$\int_{x=c}^{x=1} \frac{1}{x}\,dx = \log x\Big]_{x=c}^{x=1} = -\log c,$$

but $\lim\,(-\log c)$ as $c \to 0$ does not exist, for $-\log c$ becomes infinite as $c \to 0$.

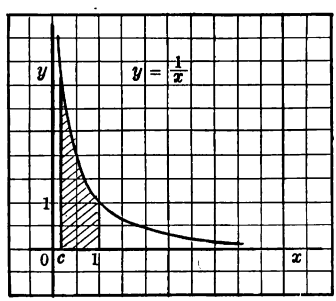

FIG. 43.

EXAMPLE 3. The area between the curve $y = 1/\sqrt[3]{x-1}$, its asymptote $x = 1$, and the line $x = 2$ is

$$\int_1^2 \frac{dx}{\sqrt[3]{x-1}} = \lim_{c\to 0}\int_{1+c}^2 \frac{dx}{\sqrt[3]{x-1}} = \frac{3}{2}\lim_{c\to 0}\,(1 - c^{2/3}) = \frac{3}{2}.$$

EXAMPLE 4. Show that $\int_{-1}^{+1} 1/x^2\,dx$ does not exist. The ordinate $y = 1/x^2$ becomes infinite as x approaches zero, *i.e.* the y-axis is a vertical asymptote. Hence to find the given integral we must proceed as above, breaking the original integral into two parts:

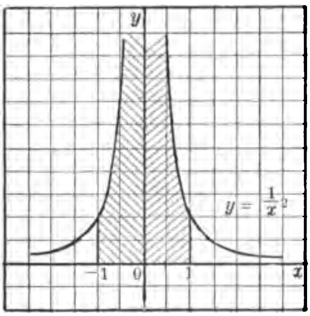

FIG. 44.

$$\mathrm{I} = \int_{x=c}^{x=1} \frac{1}{x^2}\,dx = -\frac{1}{x}\bigg]_{x=c}^{x=1} = \frac{1}{c} - 1.$$

$$\mathrm{II} = \int_{x=-1}^{x=-c} \frac{1}{x^2}\,dx = -\frac{1}{x}\bigg]_{x=-1}^{x=-c} = \frac{1}{c} - 1.$$

The limit of neither exists since $1/c$ becomes infinite as $c = 0$; hence the given integral does not exist.

Carelessness in such cases results in absurdly false answers; thus if no attention were paid to the nature of the curve, some person might write:

$$A\bigg]_{x=-1}^{x=+1} = \int_{x=-1}^{x=+1} \frac{1}{x^2}\,dx = \frac{-1}{x}\bigg]_{x=-1}^{x=+1} = -1 - 1 = -2,$$

which is ridiculous (see Fig. 44).

The only general rule is to follow the principles of §§ 115–116 in all cases of infinite limits or discontinuous integrands. Such integrals are called ***improper integrals.***

EXERCISES

Verify each of the following results.

1. $\displaystyle\int_{-1}^{+1} \frac{dx}{x^{2/3}} = 6.$

2. $\displaystyle\int_{-1}^{+1} \frac{dx}{x^3}$ is non-existent.

3. $\displaystyle\int_{0}^{1} \frac{dx}{x^n}$ is $\begin{cases}\text{determinate if } n < 1,\\ \text{non-existent if } n \geqq 1.\end{cases}$

4. $\displaystyle\int_{0}^{1} \frac{dx}{\sqrt{1-x}} = 2.$

5. $\displaystyle\int_{0}^{a} \frac{dx}{\sqrt{a-x}} = 2\sqrt{a}.$

6. $\displaystyle\int_{1.5}^{2} \frac{dx}{\sqrt{2x-3}} = 1.$

7. $\displaystyle\int_{1.5}^{2} \frac{dx}{2x-3}$ is non-existent

8. $\displaystyle\int_{1.5}^{2} \frac{dx}{(2x-3)^n}$ is $\begin{cases}\text{determinate if } n < 1,\\ \text{non-existent if } n \geqq 1.\end{cases}$

State a similar rule for $\int_a^b \frac{dx}{(hx+k)^n}$.

9. $\int_0^a \frac{dx}{\sqrt{a^2-x^2}} = \frac{\pi}{2}$.

10. $\int_0^1 \frac{x\,dx}{\sqrt{1-x^2}} = 1$.

11. $\int_0^a \frac{x^2\,dx}{\sqrt{ax-x^2}} = \frac{3\pi a^2}{8}$.

12. $\int_{-1}^{+1} \frac{dx}{x^2+5x+4}$ is non-existent.

13. Show that the integrals $\int_0^{\frac{\pi}{2}} \tan x\,dx$, $\int_0^{\frac{\pi}{2}} \operatorname{ctn} x\,dx$, $\int_0^{\frac{\pi}{2}} \sec x\,dx$, $\int_0^1 \frac{\log x\,dx}{x}$ are all non-existent.

Verify each of the following results:

14. $\int_1^\infty \frac{dx}{x^3} = \frac{1}{2}$.

15. $\int_1^\infty \frac{dx}{\sqrt[3]{x}}$ is non-existent.

16. $\int_0^\infty \frac{dx}{(1+x)^{3/2}} = 2$.

17. $\int_0^\infty \frac{dx}{(1+x)^{2/3}}$ is non-existent.

18. $\int_0^\infty \frac{dx}{(1+x)^n}$ is $\begin{cases}\text{determinate if } n > 1,\\ \text{non-existent if } n \leqq 1.\end{cases}$

19. $\int_0^\infty \frac{dx}{1+x^2} = \frac{\pi}{2}$.

20. $\int_a^\infty \frac{dx}{a^2+x^2} = \frac{\pi}{4a}$.

21. $\int_1^\infty \frac{dx}{x^2\sqrt{x^2-1}} = 1$.

22. $\int_1^\infty \frac{\sqrt{1+x}}{x}\,dx$ is non-existent.

23. $\int_0^\infty e^{-2x}\,dx = \frac{1}{2}$.

24. $\int_0^\infty e^{2x}\,dx$ is non-existent.

Determine the area between each of the following curves, the x-axis, and the ordinates at the values of x indicated.

25. $y^3(x-1)^2 = 1$; $x = 0$ to 9. *Ans.* 9.

26. $xy^2(1+x)^2 = 4$; $x = 0$ to 4. *Ans.* $4\tan^{-1} 2$.

27. $y^2x^4(1+x) = 1$; $x = 0$ to 3. *Ans.* ∞.

28. $x^2y^2(x^2-1) = 9$; $x = 1$ to 2. *Ans.* 2π.

29. $y^3(x-1)^2 = 8x^3$; $x = 0$ to 3. *Ans.* $9\sqrt[3]{2} + 9/2$.

30. $x^2y^2(x^2+9) = 1$; $x = 4$ to ∞. *Ans.* $\frac{1}{3}\log 2$.

31. $y^2(1+x)^4 = x$; $x = 0$ to ∞. *Ans.* π.

32. $y^3(x+1)^2 = 1$; $x = 0$ to ∞. *Ans.* ∞.

CHAPTER XIII

INTEGRALS AS LIMITS OF SUMS

117. Step-by-step Process. The total amount of a variable quantity whose rate of change (derivative) is given [*i.e.* the integral of the rate] can be obtained in another way. The method about to be explained has many theoretical advantages and one decidedly practical advantage, namely in its application to the approximate evaluation of integrals when the indicated integration cannot be carried out.

For example, imagine a train whose speed is increasing. The distance it travels cannot be found by multiplying the speed by the time; but we can get the total distance *approximately* by steps, computing (approximately) the distance traveled in each second as if the train were actually going at a constant speed during that second, and adding all these results to form a total distance traveled.

If the speed increases steadily from zero to 30 mi. per hour, in 44 sec., that is, from zero to 44 ft. per second in 44 sec., the increase in speed each second (acceleration) is 1 ft. per second. Hence the speeds at the beginnings of each of the seconds are 0, 1, 2, 3, $\cdots$, etc.

If we use as the speed during each second the speed at the beginning of that second, we should find the total distance (approximately)

$$s = 0 + 1 + 2 + 3 + \cdots + 42 + 43 = \frac{43 \cdot 44}{2} = 946,$$

which is evidently a little too low.

If we use as the speed during each second the speed at the end of that second, we should get (approximately)

$$s = 1 + 2 + 3 + 4 + \cdots + 43 + 44 = \frac{44 \cdot 45}{2} = 990,$$

which is evidently too high. But these values differ only by 44 ft.; and we are sure that the desired distance is between 946 and 990 ft.

If we reduce the length of the intervals, the result will be still more accurate; thus if, in the preceding example, the distances be computed by half seconds, it is easily shown that the distance is between 957 ft. and 979 ft.; if the steps are taken 1/10 second each, the distance is found to be between 965.8 ft. and 970.2 ft.

Evidently, the exact distance is the *limit* approached by this step-by-step summation as the steps Δt approach zero:

$$s\Big]_{t=0}^{t=44} = \int_{t=0}^{t=44} v\,dt = \int_{t=0}^{t=44} t dt = \frac{t^2}{2}\Big]_{t=0}^{t=44} = 968.$$

We note particularly that the two results for s are surely equal; hence we obtain the important result:

$$\int_{t=0}^{t=44} v\,dt = \lim_{\Delta t=0}\left\{ v\Big]_{t=0} \cdot \Delta t + v\Big]_{t=\Delta t} \cdot \Delta t + v\Big]_{t=2\Delta t} \cdot \Delta t + \cdots \right\}.$$

118. Approximate Summation. This step-by-step process of summation to find a given total is of such general application, and is so valuable even in cases where no limit is taken, that we shall stop to consider a few examples, in which the methods employed are either obvious or are indicated in the discussion of the example.

Thus, areas are often computed approximately by dividing them into convenient strips. We have seen in § 55 that if A denotes the area under a curve between $x = a$ and

$x = b$, then the rate of increase of A is the height h of the curve:

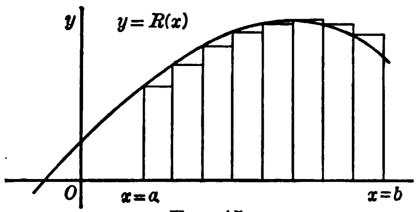

FIG. 45.

$$\frac{dA}{dx} = h = R(x),$$

where $R(x)$ is the rate of increase of A, and is also the height of the curve.

For a parabola, $h = x^2$, we may find the area A approximately between $x = -1$ and $x = 2$ by dividing that interval into smaller pieces and computing (approximately) the areas which stand on those pieces as if the height h were constant throughout each piece. If, for example, we divide the area A into six strips of equal width, each 1/2 unit wide, and if we take the height throughout each one to be the height at the left-hand corner, the total area is (approximately)

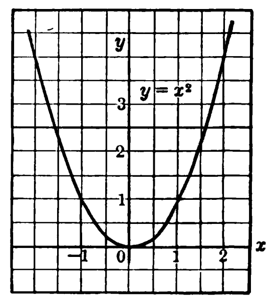

FIG. 46.

$$(-1)^2 \cdot \tfrac{1}{2} + (-\tfrac{1}{2})^2 \cdot \tfrac{1}{2} + 0 \cdot \tfrac{1}{2} + (\tfrac{1}{2})^2 \tfrac{1}{2} + (+1)^2 \tfrac{1}{2} + (\tfrac{3}{2})^2 \tfrac{1}{2} = 19/8,$$

whereas, if we take the height equal to the height at the right-hand corner we get 31/8. The area is really 3, as we find by § 55. Taking still smaller pieces, the result is of course better; thus with 30 pieces each $\frac{1}{10}$ unit wide, the left-hand heights give 2.855, the right-hand heights 3.155. With still more numerous (smaller) pieces these approximate results approach the true value of the area. (See § 119, p. 196.)

EXERCISES

Approximate to about 1% the areas under the following curves, between the limits indicated. Estimate the answers roughly in advance. Use judgment with regard to scales to gain accuracy by having the figure as large as convenient. Express each area as a definite integral and check by integration when possible.

1. $y = x^2 - 4x$; $x = 2$ to 6.
2. $y = 1/x$; $x = 10$ to 20.
3. $y = x^{-2}$; $x = 1$ to 5.
4. $y = x^{-3/2}$; $x = 2$ to 4.
5. $y = \dfrac{1-x}{x}$; $x = 2$ to 4.
6. $y = \dfrac{x}{1+x^2}$; $x = 0$ to 2.
7. $y = 1/\sqrt{12-x}$; $x = 3$ to 8.
8. $y = \sqrt{9-x}$; $x = 0$ to 5.
9. $y = 1/\sqrt{9-x^2}$; $x = 0$ to 1.5.
10. $y = \sqrt{9+x^2}$; $x = 0$ to 4.
11. $y = \dfrac{\cos x}{1+\sin^2 x}$; $x = 0$ to $\pi/2$.
12. $y = \dfrac{1}{e^x + e^{-x}}$; $x = 0$ to 1.
13. $y = \dfrac{1}{(4+x^2)^{3/2}}$; $x = 0$ to 2.
14. $y = \dfrac{1}{\sqrt{1-x^3}}$; $x = 0$ to .5.
15. $y = \sqrt{9+x^4}$; $x = 0$ to 2.
16. $y = (1-\cos x)^{3/2}$; $x = 0$ to 2π.
17. $y = \dfrac{1}{\sqrt{4-\sin^2 x}}$; $x = 0$ to $\pi/6$.
18. $y = \tan^{-1} x$; $x = 0$ to 1.
19. $y = \dfrac{\cos x}{1+\sin x}$; $x = 0$ to $\pi/2$.
20. $y = \sqrt{\dfrac{4-x^2}{1-x^2}}$; $x = 0$ to .5.
21. $y = e^{-x^2}$; $x = 0$ to 1.
22. $y = x\,e^{-x^2}$; $x = 0$ to 1.

Approximate to about 1% the distance passed over between the indicated time limits, when the speed is as below; express each distance as a definite integral, and check by integration when possible.

23. $v = 4t + t^2$; $t = 1$ to 3.
24. $v = \dfrac{1-t}{1+t}$; $t = 0$ to 50.
25. $v = \dfrac{1}{2t+t^2}$; $t = 1$ to 4.
26. $v = \dfrac{1}{1+\sqrt{t}}$; $t = 0$ to 100.
27. $v = \dfrac{t}{3+t^2}$; $t = 1$ to 3.
28. $v = \sqrt[3]{1+t^2}$; $t = 10$ to 20.

29. Show how to find the volume of a cone approximately, by adding together layers perpendicular to its axis.

30. Find the volume of a sphere by imagining it divided into small pyramids with their vertices at the center and their bases in the surface, as in elementary geometry.

31. The volume of a ship is computed by means of the areas of cross sections at small distances from each other; show how the result is calculated. Show how to make a more accurate computation by the same method.

119. Exact Results. Summation Formula. Any definite integral

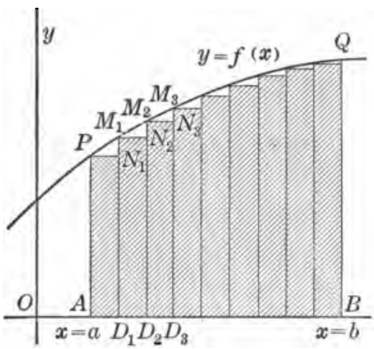

FIG. 47.

$$(1) \qquad \int_{x=a}^{x=b} f(x)\, dx$$

may be thought of as the area under a curve

$$(2) \qquad y = f(x)$$

between the ordinates $x = a$ and $x = b$.

If the interval AB from $x = a$ to $x = b$ be divided into n parts, each of width Δx, the whole area is approximately as in § 118,

$$(3)\ S = \Delta x \cdot f(a) + \Delta x \cdot f(a + \Delta x) + \cdots + \Delta x \cdot f(a + (n-1)\,\Delta x).$$

The term $\Delta x \cdot f(a)$ is the area of the rectangle AD_1N_1P, since $f(a) = AP$. Likewise $\Delta x \cdot f(a + \Delta x)$ is the area of $D_1D_2N_2M_1$, etc. Hence the sum S represents the shaded area in Fig. 47.

If the curve is rising from $x = a$ to $x = b$, as in Fig. 47, S is smaller than the area under the curve. On the other hand the similar sum

$$(4)\ R = \Delta x \cdot f(a + \Delta x) + \Delta x \cdot f(a + 2\,\Delta x) + \cdots$$
$$+ \Delta x \cdot f(a + (n-1)\,\Delta x) + \Delta x \cdot f(b)$$

is represented by the shaded area in Fig. 48, and R is too large if the curve is rising. Hence

$$R > \int_a^b f(x)\,dx > S$$

if the curve is rising. But, subtracting (3) from (4), we have

$$(5)\quad R - S = \Delta x\,[f(b) - f(a)],$$

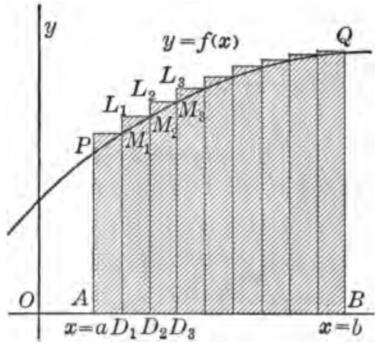

FIG. 48.

and this approaches zero as Δx approaches zero. It follows that the true value of the integral is the limit of either R or S as Δx approaches zero, *i.e.*, as n becomes infinite, and we may write *

$$(6)\quad \int_a^b f(x)\,dx = \lim_{n\to\infty} \Big\{ \Delta x\,f(a) + \Delta x\,f(a + \Delta x) + \cdots + \Delta x\,f(a + (n-1)\Delta x) \Big\},$$

at least if the curve rises from $x = a$ to $x = b$.

Similarly, the formula (6) is true also if the curve falls from $x = a$ to $x = b$. Finally, if the curve alternately rises and falls, we may prove (6) by separating the interval into several parts, in some of which it rises and in some of which it falls.

The formula (6) is called the ***summation formula of the integral calculus.***

120. Integrals as Limits of Sums. By far the greater number of integrations appear more naturally as *limits of sums* than as *reversed rates.*

* We have written (6) as the limit of S. It would be equally correct to use R, since $R-S$ approaches zero.

Thus, as a matter of fact, even the area A under a curve, treated in § 55 as a reversed rate, probably appears more *naturally* as the limit of a sum, as in (6), § 119. Of course the two are equivalent, since (6), § 119, is true; in any case the results are ***calculated*** always either ***approximately,*** as in the exercises under § 118, or else ***precisely*** by the methods of §§ 52–54. Hence the method of § 54 was given first, because it is used for each calculation even when the problem arises by a summation process.

On account of the frequent occurrence of the summation process, we may say that *an integral really means* a limit of a sum,* but when absolutely precise results are wanted *it is calculated as a reversed differentiation.* The symbol $\int$ is really a large S somewhat conventionalized, while the dx of the symbol is to remind us of the Δx which occurs in the step-by-step summation.

EXERCISES

Express each of the following integrals as the limit of a sum, as in (6), § 119. Find its approximate value to about 1%, and check by integration.

1. $\int_2^{10} \frac{x+1}{x-1}\,dx.$ **2.** $\int_0^2 \frac{x}{1+x^2}\,dx.$ **3.** $\int_0^4 \sqrt{9+x^2}\,dx.$

4. $\int_0^7 \sqrt[3]{1+x}\,dx.$ **5.** $\int_0^\pi \sin x\,dx.$ **6.** $\int_0^{\pi/2} \cos x\,dx.$

7. $\int_0^{45^\circ} \tan x\,dx.$ **8.** $\int_0^{30^\circ} \sec x\,dx.$ **9.** $\int_{10}^{50} \log_{10} x\,dx.$

* It is really a waste of time to discuss at great length here which fact about integrals is used as a definition, and which one is proved; to satisfy the demand for formal definition, the integral may be defined in either way, — as a limit of a sum, or as a reversed differentiation. The important fact is that the two ideas coincide, which is the fact stated in the Summation Formula.

Express each of the following quantities as the limit of a sum; find its approximate value to about 1%; check by integration.

10. The area under the curve $y = x^2$ from $x = 1$ to $x = 3$; from $x = -3$ to $x = 3$.

11. The area under the curve $y = x^3$ from $x = 0$ to $x = 2$; from $x = -1$ to $x = +1$.

12. The area under the curve $x^2 y = 1$ from $x = 2$ to $x = 5$.

13. The distance passed over by a body whose speed is $v = 4t + 10$ from $t = 0$ to $t = 3$.

14. The distance passed over by a falling body ($v = gt$) from $t = 2$ to $t = 6$.

15. The increase in speed of a falling body from the fact that the acceleration is $g = 32.2$, from $t = 0$ to $t = 5$.

16. The increase in the speed of a train which moves so that its acceleration is $j = t/100$, between the times $t = 0$ and $t = 6$. The distance passed over by the same train, starting from rest, during the same interval of time.

17. The number of revolutions made in 5 min. by a wheel which moves with an angular speed $\omega = t^2/1000$ (radians per second).

18. The time required by the wheel of Ex. 17 to make the first ten revolutions.

19. Repeat Ex. 18 for a wheel for which $\omega = 100 - 10t$ (degrees per second). Find the time required for the first revolution after $t = 0$; note that the speed is decreasing.

20. The weight of a vertical column of air 1 sq. ft. in cross section and 1 mi. high, given that the weight of air per cubic foot at a height of h feet is $.0805 - .00000268\,h$ pounds.

121. Volume of any Frustum. To illustrate the ease of application of this process, consider again the volume of a frustum of a solid. (See § 57.)

If such a frustum be divided up into layers of thickness Δs, by planes parallel to the base, and if A_s represents the area of any section at a distance s from the lower bounding

plane, the volume of each layer is, approximately, the product of its thickness Δs times the area A_s of the bottom of the layer:

(1) *Volume of one layer* $= A_s \Delta s$, approximately.

Now if we replace x in (3), § 119, by s, and if $A_s = f(s)$, the sum of all such layers would be, approximately,

$$\Delta s \cdot f(a) + \Delta x \cdot f(a + \Delta s) + \cdots\cdots + \Delta s \cdot f(a + (n-1)\Delta s).$$

Hence, by (6), § 119, the exact total volume is

$$V = \int_{s=a}^{s=b} A_s \, ds = \int_{s=a}^{s=b} f(s)\, ds.$$

This formula is the same as that derived in § 57. It may be used to find the volume of any solid, if we know how to find the areas of any such complete set of parallel cross sections.

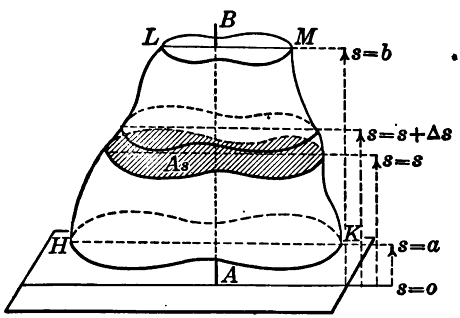

FIG. 49.

In particular, if the solid is a solid of revolution, the preceding formula reduces to formula (4) of § 56.

122. Surface of a Solid of Revolution. Similarly any such formula is readily derived, and easily remembered by means of this new process. Thus the formula for the surface of a solid of revolution was derived in § 85. To obtain that formula, or to remember it, we may remark that the curved area of any short section is approximately

$$\Delta A = 2\,\pi y\, \Delta s,$$

since the curved area is approximately the area of a section

of a cone. It follows readily that the total area of such a surface is

$$A = \int 2\,\pi y\, ds$$
$$= \int 2\,\pi y \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx.$$

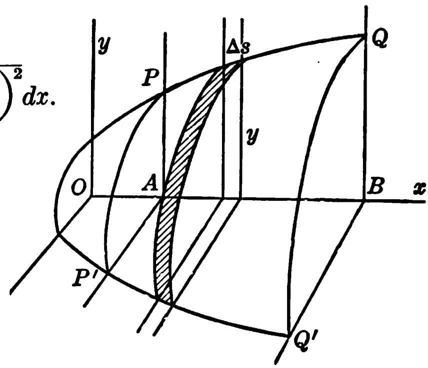

FIG. 50.

123. Water Pressure. As another typical instance, consider the water pressure on a dam or on any container. The pressure in water increases directly with the depth h, and is equal in all directions at any point. The pressure p on unit area is

(1) $$p = k \cdot h$$

where h is the depth and k is the weight per cubic unit (about 6.24 lb. per cubic foot).

Suppose water flowing in a parabolic channel, Fig. 51, whose vertical section is the parabola

$$x^2 = 225\,y.$$

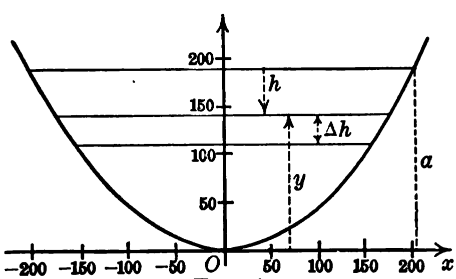

FIG. 51.

Let a be the depth of the water in the channel. If a cut-off gate be placed across the channel, let it be required to calculate the total pressure on the gate.

Consider a horizontal strip of height Δh, whose upper edge is h below the surface. The area of such a strip is its width, w, times its height, Δh. Hence the pressure on the strip is, approximately,

$$\textit{pressure on horizontal strip} = (k \cdot h)\, w \cdot \Delta h$$

In this example, $w = 2x = 2\sqrt{225\,y} = 30\,y^{1/2}$, $h = a - y$, and $\Delta y = \Delta h$. Hence

$$\textit{pressure on horizontal strip} = 30\,k\,(a - y)y^{1/2}\,\Delta y,$$

and the sum of the pressures on all such strips is the sum of such terms as this one. Hence, by (6), § 119, the correct total pressure is

$$P = 30\,k \int_{y=0}^{y=a} (a - y)\; y^{1/2}\,dy$$

$$= 30\,k\left[\frac{ay^{3/2}}{3/2} - \frac{y^{5/2}}{5/2}\right]_0^a = 8\,ka^{5/2},$$

where $k = 62.4$ lb., and a is the total depth of the water.

EXERCISES

1. Find the volume generated by revolving $\sqrt{x} + \sqrt{y} = \sqrt{a}$ about the x-axis, from $x = 0$ to $x = a$.

2. Find the volume of the paraboloid $z = x^2/a^2 + y^2/b$, from $z = 0$ to h.

3. Find the volume of the cone $z^2 = x^2/a^2 + y^2/b^2$, from $z = 0$ to h.

4. Find the volume of a regular pyramid of base B and height h.

5. On a system of parallel chords of a circle are constructed equilateral triangles whose bases are those chords and whose planes are perpendicular to the plane of the circle. Find the volume in which all these triangles are contained.

6. On the double ordinates of an ellipse are constructed triangles of fixed height h, with planes perpendicular to the plane of the ellipse. Find the volume containing all these triangles.

7. Find the volume generated by a variable square whose center moves along the x-axis from $x = 0$ to π, the plane of the square being perpendicular to the x-axis, and the side proportional to $\sin x$.

8. Find the surface of the spheroid generated by revolving the ellipse $y^2 = (1 - e^2)(a^2 - x^2)$ about the x-axis.

9. Find the surface generated by revolving the catenary $y = (e^x + e^{-x})/2$ about the x-axis, from $x = 0$ to a.

10. As in Ex. 9 for the hypocycloid $x^{2/3} + y^{2/3} = a^{2/3}$, from $x = -a$ to a.

11. As in Ex. 9 for one arch of the cycloid.

12. Find the surface generated by revolving $\rho = a \cos \theta$ about the initial line.

13. As in Ex. 12 for the cardioid $\rho = a(1 + \cos \theta)$.

Calculate the following pressures:

14. On one side of the gate of a dry dock, the wet area of the gate being a rectangle 80 ft. long and 30 ft. deep.

15. One side of a board 10 ft. long and 2 ft. wide, which is submerged vertically in water with the upper end 10 ft. below the surface.

16. On an equilateral triangle 20 ft. on a side, submerged in water with its plane vertical and one side in the surface.

17. On one side of a square tank 10 ft. high and 5 ft. on a side, the tank being filled with a liquid of specific gravity .8.

18. On one face of a square 10 ft. on a side, submerged so that one diagonal is vertical and one corner in the surface.

19. On one end of a parabolic trough filled with water, the depth being 3 ft. and the width across the top 4 ft.

20. On one side of an isosceles trapezoid whose upper base is 10 ft. long, parallel to the surface and 10 ft. below it, whose lower base is 20 ft. and altitude 12 ft.

21. What is the effect on the pressure if all dimensions given in Ex. 20 are multiplied by a constant c?

124. Cavalieri's Theorem. The Prismoid Formula. If two solids contained between the same two parallel planes have all their corresponding sections parallel to these planes equal, *i.e.* if the area A'_s of such a section for the first solid is the same as the area A''_s of the second, it follows from § 57 that their total volumes are equal, since the two volumes are given by the same integral.

This fact, known as ***Cavalieri's Theorem,*** is often useful in finding the volumes of solids.

If the area A_s of any section of a frustum is a *quadratic function* of s: *

$$(1) \qquad A_s = as^2 + bs + c,$$

where, as in § 57, s represents the distance of the section A_s from one of the two parallel truncating planes, the volume is

$$(2) \quad V\Big]_{s=0}^{s=h} = \int_{s=0}^{s=h} (as^2 + bs + c)\,ds = \left[a\frac{s^3}{3} + b\frac{s^2}{2} + cs\right]_{s=0}^{s=h}$$
$$= \frac{ah^3}{3} + \frac{bh^2}{2} + ch,$$

where h is the total height of the frustum.

The area B of the base of the frustum, the area T of the top, and the area M of a section midway between the top and bottom are

$$B = A_s\Big]_{s=0} = \Big[as^2 + bs + c\Big]_{s=0} = c;$$
$$T = A_s\Big]_{s=h} = \Big[as^2 + bs + c\Big]_{s=h} = ah^2 + bh + c;$$
$$M = A_s\Big]_{s=h/2} = \Big[as^2 + bs + c\Big]_{s=h/2} = a\frac{h^2}{4} + b\frac{h}{2} + c.$$

If we take the *average* of B, T, and 4 times M:

$$\frac{B + T + 4M}{6} = \frac{ah^2}{3} + \frac{bh}{2} + c,$$

this average section multiplied by the total height h turns out to be *exactly* the entire volume:

$$(3) \qquad \frac{B + T + 4M}{6} \times h = \frac{ah^3}{3} + \frac{bh^2}{2} + ch = V\Big]_{s=0}^{s=h}.$$

* It is shown in Ex. 3, p. 206, that the results of this section hold also when A_s is any cubic function of s: $A_s = as^3 + bs^2 + cs + d$. Notice also that any linear function $bs + c$ is a special case of (1), for $a = 0$.

This fact is known as the ***prismoid formula.*** It is easy to see by actually checking through the various formulas, *that this formula holds for every solid whose volume is given in elementary geometry;* the same formula *holds for a great variety of other solids.** But the chief use to which the formula is put is for practical approximate computation of volumes of objects in nature: it is reasonably certain that any hill, for example, can be approximated to rather closely either by a frustum of a cone, or of a sphere, or of a cylinder, or of a pyramid, or of a paraboloid; since the prismoid formula holds for all these frusta, it is quite safe to use the formula *without even troubling to see which* of these solids actually approximates to the hill. Similar remarks apply to many other solids, such as metal castings, though it may be necessary to use the formula several times on separate portions of such a complicated object as the pedestal of a statue, or a large bell with attached support and tongue.

EXAMPLE. The prismoid formula applies to any frustum of an ellipsoid of revolution cut off by planes perpendicular to the axis of revolution.

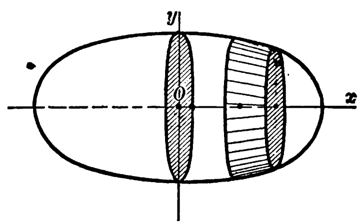

FIG. 52.

Let the origin be situated on one of the truncating planes of the frustum, and let the axis of x be the axis of revolution. Then the equa-

* The formula holds also, for example, for any *prismoid, i.e.* for a solid with any base and top sections whatever, with sides formed by straight lines joining points of the base to points of the top section. For example, any wedge, even if the base be a polygon or a curve, is a prismoid. The solids defined by (1) include all these and many others; for example, spheres and paraboloids, which are *not* prismoids. The formula holds for all these solids and even (see Ex. 3, p. 206) for all cases where A_s is any cubic function of s. One advantage of the formula is that it is easy to remember: even the formula for the volume of a sphere is most readily remembered by remembering that the prismoid formula holds.

tion of the generating ellipse is of the form $Ax^2 + By^2 + Dx + F = 0$. The area A_s of a section parallel to the bases is πy^2, since the section is a circle whose radius is y. Hence

$$A_s = \pi y^2 = \pi\left(-\frac{A}{B}x^2 - \frac{D}{B}x - \frac{F}{B}\right),$$

which is a quadratic function of the distance x from one of the truncating planes of the frustum. Therefore the prismoid formula holds.

Beware of applying the prismoid formula, as anything but an approximation formula, without knowing that the area of a section is a quadratic function of s, or (Ex. 3, p. 206) a cubic function of s.

EXERCISES

[This list includes a number of exercises which are intended for reviews.]

1. Show that the prismoid formula holds for each of the following elementary solids; hence calculate the volume of each of them by that formula: (*a*) sphere; (*b*) cone; (*c*) cylinder; (*d*) pyramid; (*e*) frustum of a sphere; (*f*) frustum of a cone. See *Tables*, II, F.

2. Calculate the volume of the solid formed by revolving the area between the curve $y = x^2$ and the x-axis about the x-axis, between $x = 1$ and $x = 3$. Find the same volume (approximately) by the prismoid formula, and show that the error is about 0.6%.

3. Calculate the volume of a frustum of a solid bounded by planes $h = 0$ and $h = H$, if the area A_S of a parallel cross section is a cubic function $ah^3 + bh^2 + ch + d$ of the distance h from one base, first by direct integration, then by the prismoid formula. Hence prove the statement of the footnote, p. 205.

4. In which of the exercises relating to volumes on p. 97 does the prismoid formula give a precise answer?

5. How much is the percentage error made in computing the volume in Ex. 7, p. 97, from $x = 1$ to $x = 3$, by use of the prismoid formula?

6. Show, by analogy to § 64, that the area under any curve whose ordinate y is any quadratic function (or any cubic function) of x, between $x = a$ and $x = b$, is

$$\frac{(b-a)}{6}\,[y_A + 4y_M + y_B],$$

where y_A, y_B, y_M represent the values of y at $x = a$, $x = b$, $x = (a + b)/2$, respectively.

Calculate, first by direct integration, and then by the rule of Ex. 6, the areas under each of the following curves:

7. $y = x^2 + 2x + 3$ between $x = 1$ and $x = 5$.

8. $y = x^2 - 5x + 4$ between $x = 0$ and $x = 5$.

9. $y = x^3 + 5x$ between $x = 2$ and $x = 4$.

10. Calculate approximately the area under the curve $y = x^4$ between $x = 1$ and $x = 3$ by the rule of Ex. 6. Show that the error is about .55%.

11. Show that any integral whose integrand $f(x)$ is a quadratic (or a cubic) function of x, can be evaluated by a process analogous to the prismoid rule:

$$\int_{x=a}^{x=b} f(x)\,dx = \left[f(a) + 4f\left(\frac{a+b}{2}\right) + f(b)\right]\frac{b-a}{6}.$$

12. Evaluate the integral $\int (1/x^2)\,dx$ between $x = 1$ and $x = 5$ approximately, first by the rule of Ex. 11; then by applying the same rule twice in intervals half as wide; then by applying the rule to intervals of unit width.

13. Show that any integral $\int f(x)\,dx$ can be computed approximately by using Ex. 11 with an even number of intervals of small width Δx:

$$\int_{x=a}^{x=b} f(x)\,dx = \Big[f(a) + 4f(a+\Delta x) + 2f(a+2\Delta x) + 4f(a+3\Delta x) + \cdots + f(b)\Big]\frac{\Delta x}{3}.$$

[This rule is called Simpson's Rule.]

Calculate the following integrals approximately by Simpson's Rule. Notice that some of them cannot be evaluated otherwise at present.

14. $\int_0^3 x^5\,dx.$ **16.** $\int_0^2 \sqrt{x}\,dx.$ **18.** $\int_0^1 \sqrt{1+x^2}\,dx.$

15. $\int_1^3 (1/x)\,dx.$ **17.** $\int_1^5 \sqrt{1+x}\,dx.$ **19.** $\int_0^{\pi/4} \sin x\,dx.$

20. Find approximately the length of the arc of the curve $y = x^2$ from $x = 0$ to $x = \frac{1}{2}$; from $x = \frac{1}{2}$ to $x = 1$.

21. Find approximately the area of the convex surface of that portion of the paraboloid formed by revolving the curve $y = \sqrt{x}$ about the x-axis which is cut off by the planes $x = 0$ and $x = \frac{1}{2}$; by $x = \frac{1}{2}$ and $x = 1$.

CHAPTER XIV

MULTIPLE INTEGRALS — APPLICATIONS

125. Repeated Integration. Repeated integrations may be performed with no new principles. Thus

$$\int \frac{1}{x^2}\,dx = -\frac{1}{x} + c; \quad \text{and} \quad \int\left(-\frac{1}{x} + c\right)dx = -\log x + cx + c'.$$

The final answer might be called *the second integral* of $1/x^2$.

Thus, in the case of a falling body, the tangential acceleration is constant:

$$j_T = \frac{dv}{dt} = -g,$$

where g is the constant; hence

$$v = \int j_T\,dt + \text{const.} = -gt + c;$$

but since $v = ds/dt$,

$$s = \int v\,dt + \text{const.} = \int(-gt + c)\,dt + \text{const.} = -\frac{gt^2}{2} + ct + c'.$$

If the body falls from a height of 100 ft., with an initial speed zero, $s = 100$ and $v = 0$ when $t = 0$; hence $c = 0$ and $c' = 100$, whence we find

$$s = -gt^2/2 + 100.$$

The equations $s = \int v\,dt + \text{const.}$, $v = \int j_T\,dt + \text{const.}$, just obtained, apply in any motion problem, where j_T is the *tangential acceleration*, v is the *speed*, and s is the *distance* passed over.

126. Successive Integration in Two Letters. A distinctly different case of successive integration which can be performed without further rules is that in which the second integration is performed with respect to a different letter.

Thus, the volume of any solid is (§ 57),

$$(1) \qquad V = \int_{h=a}^{h=b} A_s \, dh,$$

where A_s is the area of a section perpendicular to the direction in which h is measured, and where $h = a$ and $h = b$ denote planes which bound the solid.

In many cases it is convenient first to find A_s by a first integration, by the methods of § 55, and then integrate A_s to find V by (1), this second integration being with respect to the height h.

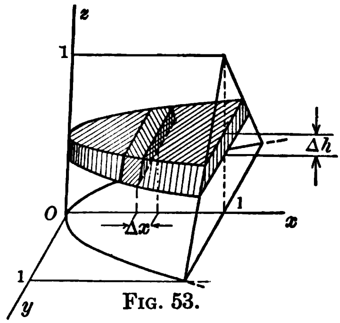

FIG. 53.

EXAMPLE 1. Find the volume of the parabolic wedge

$$y^2 = x(1 - z)^2$$

between the planes $z = 0$ and $z = 1$ and between the planes $x = 0$ and $x = 1$.

The area A_s of a section by any plane $z = h$ parallel to the xy-plane is twice the area between the curve $y = (1 - h)\sqrt{x}$ and the x-axis:

$$A_s\Big]_{x=0}^{x=1} = 2\int_{x=0}^{x=1} y\,dx = 2\int_{x=0}^{x=1} (1-h)\sqrt{x}\,dx = \frac{4}{3}(1-h)\,x^{3/2}\Big]_{x=0}^{x=1}$$
$$= \frac{4}{3}(1-h),$$

hence this volume, by (1), is

$$V\Big]_{h=0}^{h=1} = \int_{h=0}^{h=1} A_s\,dh = \frac{4}{3}\int_{h=0}^{h=1}(1-h)\,dh = \frac{4}{3}\left(h - \frac{h^2}{2}\right)\Big]_{h=0}^{h=1} = \frac{2}{3}.$$

Notice that h, during the first integration, was essentially constant.

Combining the formulas used in this example, the volume V may be written

$$V\Big]_{h=0}^{h=1} = \int_{h=0}^{h=1}\left[2\int_{x=0}^{x=1}(1-h)\sqrt{x}\,dx\right]dh = \frac{2}{3}.$$

This result is usually written without the brackets on the right:

$$V\Big]_{h=0}^{h=1} = 2\int_{h=0}^{h=1}\int_{x=0}^{x=1}(1-h)\sqrt{x}\,dx\,dh.$$

Such double integrals in two letters are very common in applications.

Examples of triple integrals will be found further on in this chapter.

127. Volumes. Double Integrals. Analogous to the problem of finding the area under a given portion of a curve, (§§ 55, 119), there is the problem of finding the volume under a given portion of a surface.* This leads to ***double integrals.***

Let $A'B'C'D'$ be a portion of a curved surface whose equation is

$$z = F(x, y).$$

Let $ABCD$ be the projection of $A'B'C'D'$ on the xy plane, curve CD being the projection of curve $C'D'$.

The problem is to express the volume between the portion $A'B'C'D'$ of the surface and its projection on the xy-plane.

Divide this volume into slices of thickness $PQ = \Delta x$, by planes parallel to the yz-plane, and further subdivide the slices into prismatic columns by planes parallel to the xy-plane spaced at intervals Δy.

The area of the section $PSS'P'$ depends on the position

* See *Tables*, I, b, for formulas from Solid Analytic Geometry.

of P, hence on x, and is therefore a function of x. Therefore by the frustum formula (§ 57), the required volume is

$$V\Big]_{x=a}^{x=b} = \int_{x=a}^{x=b} A_x\,dx.$$

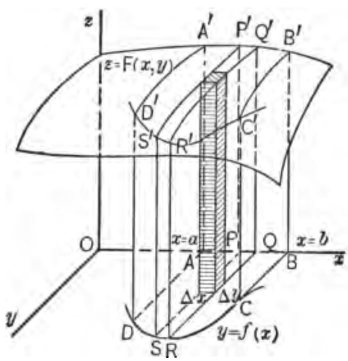

FIG. 54.

But the area A_x is the area under the curve $P'S'$ whose ordinates (heights above xy-plane) are $z = F(x, y)$, where x has the fixed value OP and y alone varies from $y = 0$ to $y = PS = f(x)$, this being the equation of curve DC, supposed given. Hence

$$A_x = \int_{y=0}^{y=f(x)} F(x, y)\,dy.$$

Then

$$V\Big]_a^b = \int_{x=a}^{x=b} A_x\,dx,$$

or

(1) $$V\Big]_a^b = \int_{x=a}^{x=b}\int_{y=0}^{y=f(x)} F(x, y)\,dy\,dx.$$

This is essentially the same sort of problem as that discussed in § 126.

This double integral may be written as the limit of a double sum. For if we consider the prismatic column on $\Delta x\,\Delta y$ as base, its volume approximately is $z\,\Delta x\,\Delta y$ or $F(x, y)\,\Delta y\,\Delta x$.

This suggests the double sum

$$\lim_{\Delta x\to 0}\sum_{x=a}^{x=b}\Big[\lim_{\Delta y\to 0}\sum_{y=0}^{y=f(x)} F(x, y)\,\Delta y\Big]\Delta x$$

or, as it is usually written,

$$\lim_{\Delta x\to 0}\sum_{x=a}^{x=b}\lim_{\Delta x\to 0}\sum_{y=0}^{y=f(x)} F(x, y)\,\Delta y\,\Delta x.$$

Here the limit of the inner summation is merely A, and then the limit of the outer summation is the integral of A or the volume. Hence we write the formula

$$(2) \quad \lim_{\substack{\Delta x\to 0\\ \Delta y\to 0}} \sum_{x=a}^{x=b} \sum_{y=0}^{y=f(x)} F(x, y)\, \Delta y\, \Delta x = \int_{x=a}^{x=b} \int_{y=0}^{y=f(x)} F(x, y)\, dy\, dx.$$

This is the fundamental summation formula for double integrals.

EXAMPLE. Determine the volume under the surface $z = x^2 + y^2$ between the xz-plane, the planes $x = 0$, $x = 1$, and $y = 0$, and the cylinder $y = \sqrt{x}$.

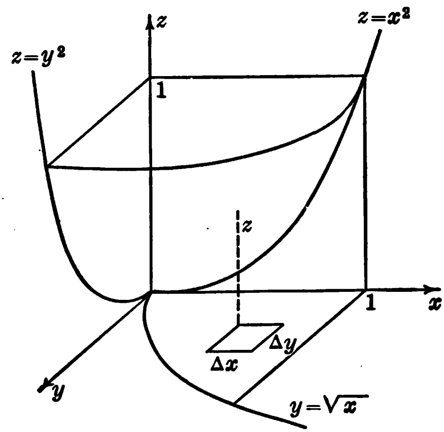

FIG. 55.

$$V = \int_{x=0}^{x=1} \int_{y=0}^{y=\sqrt{x}} (x^2 + y^2)\, dy\, dx$$

$$= \int_{x=0}^{x=1} \left[x^2 y + y^3/3\right]_0^{\sqrt{x}} dx$$

$$= \int_0^1 \left[x^{5/2} + (1/3)\, x^{3/2}\right] dx = 44/105.$$

EXERCISES

1. Determine a function $y = f(x)$ whose second derivative d^2y/dx^2 is $6x$. *Ans.* $y = x^3 + C_1x + C_2$.

2. Determine the speed v and the distance s passed over by a particle whose tangential acceleration d^2s/dt^2 is $12t$. Find the values of the arbitrary constants if $v = 0$ and $s = 0$ when $t = 0$; if $v = 100$ and $s = 0$ when $t = 0$.

Find the general expressions for functions whose derivatives have the following values:

3. $d^2y/dx^2 = 6x^2$. **6.** $d^2r/d\theta^2 = 1/\sqrt{1-\theta}$. **9.** $d^2y/dx^2 = e^x$.

4. $d^2s/dt^2 = 3 + 2t$. **7.** $d^3r/d\theta^3 = \theta^2 - 2\theta$. **10.** $d^2s/dt^2 = \sec^2 t$.

5. $d^2s/dt^2 = \sqrt{1-t}$. **8.** $d^3v/du^3 = 1 - u^2$. **11.** $d^3v/du^3 = 1/u^2$.

Determine the speed v and distance s passed over in time t, when the tangential acceleration j_T and initial conditions are as below:

12. $j_T = \sin t$; $v = 0$ and $s = 0$ when $t = 0$.

13. $j_T = t + \cos t$; $v = 0$ and $s = 0$ when $t = 0$.

14. $j_T = \sqrt{1+t}$; $v = 3$ and $s = 0$ when $t = 0$.

15. $j_T = t/\sqrt{1+t^2}$; $v = 1$ and $s = 0$ when $t = 0$.

Evaluate each of the following integrals, taking the inner integral sign with the inner differential:

16. $\int_{x=0}^{x=1}\int_{y=0}^{y=1} xy\,dy\,dx$.

17. $\int_{x=0}^{x=2}\int_{y=1}^{y=2} 6x^2(2-y)dy\,dx$.

18. $\int_{x=0}^{x=2}\int_{y=2}^{y=3}(x^2+1)(4-y^2)\,dy\,dx$.

19. $\int_{v=2}^{v=4}\int_{u=1}^{u=2}\sqrt{u+v}\,du\,dv$.

20. $\int_{x=1}^{x=e}\int_{y=0}^{y=\pi}\frac{\sin y}{x}\,dy\,dx$.

21. $\int_{t=1}^{t=3}\int_{s=-2}^{s=0}\int_{r=0}^{r=3}\frac{r^2s^2}{t^3}\,dr\,ds\,dt$.

22. $\int_{x=-1}^{x=+1}\int_{y=-x^2}^{y=+x^2}(x+y)\,dy\,dx$.

23. $\int_{x=0}^{x=3}\int_{y=1}^{y=2x+3}(x+y)^2\,dy\,dx$.

24. $\int_0^1\int_{-x}^{+x}\int_0^{x+y}(x+y+z)\,dz\,dy\,dx$.

25. $\int_0^r\int_0^{\pi}\int_0^{\pi/2} r^2\sin\theta\,d\theta\,d\phi\,dr$.

26. Find the volume of the part of the elliptic paraboloid $4x^2 + 9y^2 = 36z$ between the planes $z = 0$ and $z = 1$; between the planes $z = a$ and $z = b$.

27. Find the volume of the part of the cone $3x^2 + 9y^2 = 27z^2$ between the planes $z = 0$ and $z = 2$; between $z = a$ and $z = b$.

28. Find the volume of the part of the cylinder $x^2 + y^2 = 25$ between the planes $z = 0$ and $z = x$; between the planes $z = x/2$ and $z = 2x$.

29. A parabola, in a plane perpendicular to the x-axis and with its axis parallel to the z-axis, moves with its vertex along the x-axis. Its latus rectum is always equal to the x-coordinate of the vertex. Find the volume inclosed by the surface so generated, from $z = 0$ to $z = 1$ and from $x = 0$ to $x = 1$.

30. Find the volume of the part of the cylinder $x^2 + y^2 = 9$ lying within the sphere $x^2 + y^2 + z^2 = 16$.

31. For a beam of constant strength the deflection y is given by the fact that the flexion is constant: $b = d^2y/dx^2 =$ const. if the beam is of uniform thickness. Find y in terms of x and determine the arbitrary constants if $y = 0$ when $x = \pm l/2$. [This will occur if the beam is of length l, and is supported freely at both ends.]

32. Determine the arbitrary constants in the case of the beam of Ex. 31, if $y = 0$ and $dy/dx = 0$ when $x = 0$. [This will occur if the beam is rigidly embedded at one end.]

33. For a beam of uniform cross section loaded at one end and rigidly embedded at the other, $b = d^2y/dx^2 = k(l - x)$ where l is the length of the beam, x is the distance from one end, and k is a known constant which is determined by the load and the cross section of the beam. Find y in terms of x, and determine the arbitrary constants.

Find y in terms of x in each of the following cases:

34. $d^2y/dx^2 = k(l^2 - 2lx + x^2)$; $y = 0$, $dy/dx = 0$ when $x = 0$.

[Beam rigidly embedded at one end, loaded uniformly.]

35. $d^2y/dx^2 = a + bx$; $y = 0$, $dy/dx = 0$ when $x = 0$.

[Beam of uniform strength of thickness proportional to $(a + bx)^{-1}$, embedded at one end.]

36. $d^2y/dx^2 = k(l^2/8 - x^2/2)$; $y = 0$ when $x = \pm l/2$.

[Beam supported at both ends, loaded uniformly.]

37. $d^2y/dx^2 = k/x^2$; $y = 0$, $dy/dx = 0$ at $x = l$.

[Beam of uniform strength of thickness proportional to x^2, embedded at $x = l$.]

38. Find the angular speed ω and the total angle θ through which a wheel turns in time t, if the angular acceleration is $\alpha = d^2\theta/dt^2 = 2t$, and if $\theta = \omega = 0$ when $t = 0$.

128. Triple and Multiple Integrals. There is no difficulty in extending the ideas of §§ 126–7 to threefold integrations or to integrations of any order. Following the same reasoning, it is possible to show that, if $w = F(x, y, z)$

$$\lim_{\substack{\Delta x \to 0 \\ \Delta y \to 0 \\ \Delta z \to 0}} \sum_{z=e}^{z=f} \sum_{y=c}^{y=d} \sum_{x=a}^{x=b} w \, \Delta x \, \Delta y \, \Delta z$$

$$= \int_{z=e}^{z=f} \int_{y=c}^{y=d} \int_{x=a}^{x=b} F(x, y, z) \, dx \, dy \, dz,$$

where the three integrations are to be carried out in succession, where the limits for x may depend on y and z, and where the limits for y may depend on z: but the limits for z are, of course, constants.

Thus it is readily seen that the volume mentioned in § 127 may be computed by dividing up the entire volume by three sets of equally spaced planes parallel to the three coordinate planes. Then the total volume is, approximately, the sum of a large number of rectangular blocks, the volume of each of which is $\Delta x \, \Delta y \, \Delta z$; and its exact value is

$$V = \lim_{\substack{\Delta x \to 0 \\ \Delta y \to 0 \\ \Delta z \to 0}} \sum_{x=a}^{x=b} \sum_{y=0}^{y=f(x)} \sum_{z=0}^{z=F(x,y)} \Delta z \, \Delta y \, \Delta x$$

$$= \int_{x=a}^{x=b} \int_{y=0}^{y=f(x)} \int_{z=0}^{z=F(x,y)} dz \, dy \, dx,$$

which reduces to the result of § 127, if we note that

$$\int_{z=0}^{z=F(x,y)} dz = z \Big]_{z=0}^{z=F(x,y)} = F(x, y).$$

129. Plane Areas by Double Integration. To find the area bounded by a closed curve C, we divide it into small elements of area, either by lines drawn parallel to the coordinate axes if the equation of C is given in rectangular coordinates,

or by a system of radial lines and concentric circles if the equation of C is given in polar coordinates. (Figures 56, 57.)

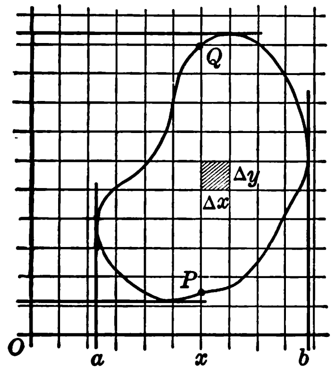

Fig. 56.

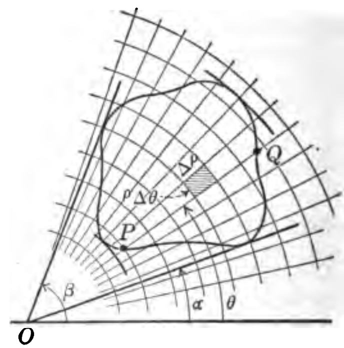

Fig. 57.

In Fig. 56 let any ordinate whose abscissa is x meet the boundary of the area in P and Q, the corresponding values of y being y_1 and y_2. Let the extreme values of x between which the oval lies be $x = a$ and $x = b$. Then the area will be

$$(1) \qquad A = \lim_{\substack{\Delta x \to 0 \\ \Delta y \to 0}} \sum_{x=a}^{x=b} \sum_{y=y_1}^{y=y_2} \Delta y \, \Delta x = \int_{x=a}^{x=b} \int_{y=y_1}^{y=y_2} dy \, dx.$$

This is merely a special case of (2), § 127, when $F(x, y) = 1$, because the volume of a right cylinder of height 1 equals the area of the cross section.

In Fig. 57 let any radius vector whose angle is θ meet the boundary of the area in P and Q, the corresponding values of ρ being $OP = \rho_1$, $OQ = \rho_2$. Let the extreme values of θ be $\theta = \alpha$ and $\theta = \beta$. Then the element of area is approximately $\rho\Delta\theta \cdot \Delta\rho$ and the total area is

$$(2) \qquad A = \lim_{\substack{\Delta\rho \to 0 \\ \Delta\theta \to 0}} \sum_{\theta=\alpha}^{\theta=\beta} \sum_{\rho=\rho_1}^{\rho=\rho_2} \rho\Delta\rho\,\Delta\theta = \int_{\theta=\alpha}^{\theta=\beta} \int_{\rho=\rho_1}^{\rho=\rho_2} \rho\, d\rho\, d\theta.$$

In formulas (1) and (2) the first integration can be carried out at once, giving

$$(1') \quad A = \int_a^b (y_2 - y_1)\, dx \qquad (2') \quad A = \int_\alpha^\beta \tfrac{1}{2}\,(\rho_2^2 - \rho_1^2)\, d\theta.$$

The last results may also be derived from the formula of § 55 and § 92, so formulas (1) and (2) may be dispensed with so far as the mere calculation of plane areas is concerned. We shall, however, find the idea of a plane area as the limit of a double sum very useful in the following sections.

EXAMPLE 1. Find the area between the parabola $y^2 = 4(x-1)$ and the line $y = x - 1$. (Fig. 58.)

The extreme values of x are found to be $x = 1$ and $x = 5$. Hence

$$A = \int_{x=1}^{x=5} \int_{y=x-1}^{y=2\sqrt{x-1}} dy\, dx = \int_1^5 \Big[2\sqrt{x-1} - (x-1) \Big] dx$$
$$= \Big[4/3\,(x-1)^{3/2} - \tfrac{1}{4}\,(x-1)^2 \Big]_1^5 = 8/3.$$

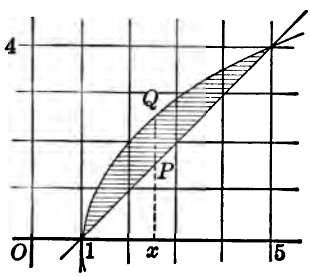

FIG. 58.

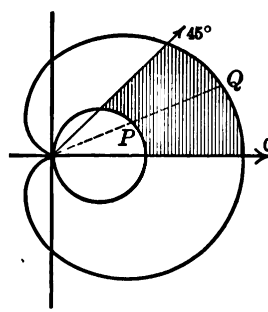

FIG. 59.

EXAMPLE 2. Find the area between the circle $\rho = \cos\theta$ and the cardioid $\rho = 1 + \cos\theta$, from $\theta = 0$ to $45°$. (Fig. 59.)

$$A = \int_{\theta=0}^{\theta=\pi/4} \int_{\rho_1=\cos\theta}^{\rho_2=1+\cos\theta} \rho\, d\rho\, d\theta$$
$$= \int_0^{\pi/4} \tfrac{1}{2}\,[(1+\cos\theta)^2 - \cos^2\theta]\, d\theta$$
$$= \tfrac{1}{2}\int_0^{\pi/4} (1 + 2\cos\theta)\, d\theta = \tfrac{1}{2}\,(\pi/4 + \sqrt{2}).$$

EXERCISES — DOUBLE INTEGRALS

1. Find the volume under the surface $z = x^2 + y^2$ between the xz-plane, the planes $x = 0$ and $x = 1$, and the cylinder whose base is the curve $y = x^2$.

Find the volume between the xy-plane and each of the following surfaces cut off by the planes and surfaces mentioned in each case:

2. $z = x + y$ cut off by $y = 0$, $x = 0$, $x = 1$, $y = \sqrt{x}$.

3. $z = x^2 + y$ cut off by $y = 0$, $x = 1$, $x = 3$, $y = x^2$.

4. $z = xy$ cut off by $y = 0$, $x = 2$, $x = 4$, $y = x^2 + 1$.

5. $z = xy + y^2$ cut off by $y = 0$, $x = 1$, $x = 5$, $y = x^3$.

6. $z = y + \sqrt{x}$ cut off by $y = 0$, $x = 0$, $x = 1$, $y = x^5$.

7. $z = x^2 + y^3$ cut off by $x = 0$, $y = 1$, $y = 4$, $y^2 = x$.

8. $z = \sqrt{x + y}$ cut off by $x = 0$, $y = 2$, $y = 5$, $y = x$.

9. $z = x^2 + 4y^2$ cut off by $y = 0$ and $y = 1 - x^2$.

10. $z = xy$ cut off by $y = x^2$ and $y = 1$.

11. $z = x^2 - y^2$ cut off by $y = x^2$ and $y = x$.

12. Find the volume of the portion of the paraboloid $z = 1 - x^2 - 4y^2$ which lies in the first octant.

13. If two plane cuts are made to the same point in the center of a circular cylindrical log, one perpendicular to the axis and the other making an angle of 45° with it, what is the volume of the wedge cut out?

14. Show that the volume common to two equal cylinders of radius a which intersect centrally at right angles is $16\,a^3/3$.

15. Show that the volume of the ellipsoid $x^2/16 + y^2/9 + z^2/4 = 1$ is $32\,\pi$.

16. How much of the ellipsoid in Ex. 15 lies within a cube whose center is at the origin and whose edges are 6 units long and parallel to the coördinate axes?

17. Where should a plane perpendicular to the x-axis be drawn so as to divide the volume of the ellipsoid in Ex. 15 in the ratio 2:1?

Calculate by double integration the areas bounded by the following curves:

18. $y = x^2$ and $y = \sqrt{x}$.

19. $y = x^2$ and $y = x^3$.

20. $y = x^2$ and $-x^2 + y^2 = 2$.

21. $x^2 + y^2 = 12$ and $y = x^2$.

22. $x = 0$, $y = \sin x$, and $y = \cos x$.

23. $y = 0$, $y^2 = x$, and $x^2 - y^2 = 2$.

24. $y = 2x$, $y = 0$, and $y = 1 - x$.

25. $y^2 = x$, and $y = 1 - x$.

Determine the entire area, or the specified portion of the area, bounded by each of the following curves, whose equations are given in polar coordinates:

26. $\rho = 2 \cos \theta$.

27. One loop of $\rho = \sin 2\theta$.

28. One loop of $\rho = \sin 3\theta$.

29. The cardioid $\rho = 1 - \cos \theta$.

30. The lemniscate $\rho^2 = \cos 2\theta$.

31. The spiral $\rho = \theta$, from $\theta = 0$ to π.

32. The spiral $\rho\theta = 1$, from $\theta = \pi/4$ to $\pi/2$.

33. $\rho = 1 + 2 \cos \theta$, from $\theta = 0$ to π.

34. $\rho = \tan \theta$, from $\theta = 0$ to $45°$.

35. $\rho = a\theta^2$, one turn.

36. $\rho = 3 \cos \theta + 2$.

37. $\rho = a \sin \theta \cos \theta / (\sin^3 \theta + \cos^3 \theta)$; folium: the loop.

130. Moment of Inertia. When a particle of mass m revolves in a plane about a point O, with given angular speed ω, its speed is $v = r\omega$, and its kinetic energy is $E = 1/2\, mv^2 = 1/2\, mr^2\omega^2$. The moment of inertia of m about O is defined as the product of the mass m by the square of its distance from O, $I = r^2 m$. Thus E is easily found where I is known.

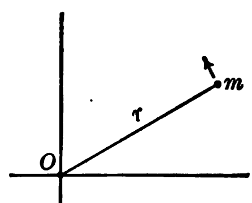

FIG. 60.

Given now a thin plate of metal of uniform density and thickness, whose boundary C is a given curve, let us divide the plate into small squares by lines equally spaced parallel to two rectangular axes through O. Let P be a point in any one of these squares and let $OP = r = \sqrt{x^2 + y^2}$. Then the mass of

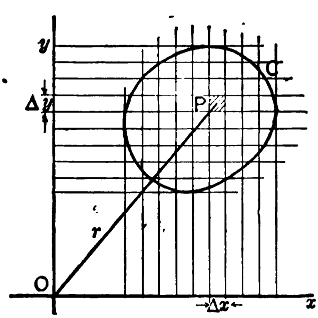

FIG. 61.

the square is $k \cdot \Delta y\, \Delta x$ where k denotes the constant surface density (*i.e.* the mass per square unit); and the moment of inertia of this square about O is, approximately, $k \cdot r^2\, \Delta y\, \Delta x$. Hence the moment of inertia I of the entire plate about O is:

$$I_0 = \lim_{\substack{\Delta y \to 0 \\ \Delta x \to 0}} \sum \sum kr^2\, \Delta x\, \Delta y = \int \int k(x^2 + y^2)\, dy\, dx.$$

The limits of integration are to be taken so as to cover the area, as in § 129.

Thus the moment of inertia of a plate bounded by the two curves $y = (1 - x^2)$ and $y = (x^2 - 1)$, about the origin (draw the figure) is:

$$\begin{aligned} I &= k \int_{x=-1}^{x=+1} \int_{y=x^2-1}^{y=1-x^2} (x^2 + y^2)\, dy\, dx \\ &= k \int_{x=-1}^{x=+1} \left[x^2 y + \frac{y^3}{3} \right]_{y=x^2-1}^{y=1-x^2} dx \\ &= \frac{2\,k}{3} \int_{x=-1}^{x=+1} (1 - x^6)\, dx = \frac{2\,k}{3} \left[x - \frac{x^7}{7} \right]_{x=-1}^{x=+1} = \frac{8}{7} k, \end{aligned}$$

where k is the surface density.

The moment of inertia about an axis is defined similarly, the distance r being replaced by the distance of P from the given axis. Thus the moments of inertia of the plate in the figure about the x- and y-axes are, respectively,

$$I_x = k \int \int y^2\, dy\, dx; \quad I_y = k \int \int x^2\, dy\, dx.$$

The radius of gyration of an area, whether about a point or about an axis, is defined by

$$\textit{radius of gyration} = K = \sqrt{I/M}.$$

If the boundary of the plate is given in *polar coordinates*, the moment of inertia about O is calculated by dividing the area into elements $r\, \Delta\theta\, \Delta r$. (See § 129.) Then

$$I_0 = \lim_{\substack{\Delta \rho \to 0 \\ \Delta\theta \to 0}} k \sum_{\theta=\alpha}^{\theta=\beta} \sum_{r=r_1}^{r=r_2} r^2 \cdot r\, \Delta\theta\, \Delta r = k \int_{\theta=\alpha}^{\theta=\beta} \int_{r=r_1}^{r=r_2} r^3 dr\, d\theta.$$

Thus for a circle whose center is O, $r = f(\theta) = a$, the radius. Hence the moment of inertia of a circular disk about its center is:

$$I_0 = k \cdot \int_{\theta=0}^{\theta=2\pi} \left[\frac{\rho^4}{4}\right]_{\rho=0}^{\rho=a} d\theta = k \cdot \int_{\theta=0}^{\theta=2\pi} \frac{a^4}{4} d\theta = \pi k \frac{a^4}{2} = \frac{Ma^2}{2},$$

where k is the surface density, and $M = k\pi a^2$ is the mass of disk.

131. Moments of Inertia in General. The moment of inertia of any mass about a given point may be defined as follows.

Divide the mass M into elements of mass Δm; multiply each element Δm by the square of its distance, r^2, from the given point; the limit of the sum of these products is the required moment of inertia:

$$(1) \qquad I = \lim_{\Delta m \to 0} \sum r^2 \Delta m = \int r^2 dm.$$

When M is a plate we take $\Delta m = k\Delta A$, where k is the mass per unit area, and $\Delta A = \Delta y\, \Delta x$ or $r \Delta\, \theta\, \Delta r$, as in § 129.

When M is a thin wire bent into the form of a given curve, $\Delta m = k\Delta s$, where k is the mass per unit length and Δs the element of length.

Then

$$(2) \qquad I = \sum kr^2 \Delta s = k \int r^2\, ds,$$

the limits beirg taken to cover the given curve. For ds we use (1) of § 82 or (1) of § 93.

When M is a solid body, we take $\Delta m = k\Delta V$, where k is the mass per unit volume and ΔV is the element of volume, $\Delta x\ \Delta y\ \Delta z$.

Then

$$(3) \qquad I = \lim_{\substack{\Delta x \to 0 \\ \Delta y \to 0 \\ \Delta z \to 0}} k \sum\sum\sum r^2\, \Delta x\, \Delta y\, \Delta z = k \iiint r^2\, dx\, dy\, dz.$$

The limits of integration are to be taken to cover the given volume.

For the moment of inertia about an axis we let r in forms (1), (2), (3), be the distance of Δm from that axis.

EXAMPLE 1. Find I for a wire bent into the form of a circular quadrant, about the center.

$$I = \int kr^2\,ds.$$

Using polar coordinates, $ds = rd\,\theta$, and

$$I = k\int_0^{\pi/2} r^3\,d\theta = kr^3\int_0^{\pi/2} d\theta$$
$$= kr^3\,\pi/2 = Mr^2, \text{ since } M = k\pi\,r/2.$$

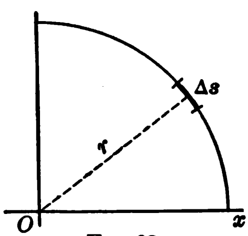

FIG. 62.

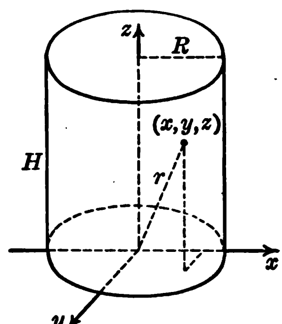

FIG. 63.

EXAMPLE 2. Find I for a circular cylinder of height H and radius R about the center of one base.

The equation of the surface is $x^2 + y^2 = R^2$, if the z-axis is the axis of the cylinder. Then, by symmetry,

$$I = 4\,k\int_{x=0}^{x=R}\int_{y=0}^{y=\sqrt{R^2-x^2}}\int_{z=0}^{z=H}(x^2+y^2+z^2)\,dz\,dy\,dx,$$
$$= 4\,k\int_{x=0}^{x=R}\int_{y=0}^{y=\sqrt{R^2-x^2}}(x^2H + y^2H + H^3/3)\,dy\,dx$$
$$= 4\,kH\int_{x=0}^{x=R}(x^2y + y^3/3 + H^2y/3)\Big|_0^{\sqrt{R^2-x^2}}dx$$
$$= 4\,kH\int_{x=0}^{x=R}(x^2\sqrt{R^2-x^2} + (R^2-x^2)^{3/2}/3 + H^2\sqrt{R^2-x^2}/3)\,dx.$$

Let $x = R \sin \theta$. Then

$$I = 4\,kHR^2 \int_0^{\pi/2} (R^2 \sin^2 \theta \cos^2 \theta + R^2 \cos^4 \theta/3 + H^2 \cos^2 \theta/3)\,d\theta$$
$$= 4\,kHR^2\,(R^2\,\pi/16 + R^2\,\pi/16 + 16 + H^2\,\pi/12)$$
$$= kHR^2\,(3\,R^2 + 2\,H^2)\,(\pi/6).$$

EXERCISES

Calculate I about the origin for the areas bounded by the following curves (Density $= k = 1$):

1. $y = x^2$ and $y = \sqrt{x}$.
2. $y = x^2$ and $y = x^3$.
3. $y = x^2$ and $-x^2 + y^2 = 2$.
4. $x^2 + y^2 = 12$ and $y = x^2$.
5. $x = 0$, $y = \sin x$, and $y = \cos x$
6. $y = 0$, $y^2 = x$, and $x^2 - y^2 = 2$.
7. $y = 2\,x$, $y = 0$, and $y = 1 - x$.
8. $y^2 = x$, and $y = 1 - x$.

Find the moment of inertia and radius of gyration of each of the following shapes of thin plate:

9. A square about a diagonal. About a corner.
10. A right triangle about a side. About the vertex of the right angle.
11. A circle about its center.
12. An ellipse about either axis. About the center.
13. A circle about a diameter.
14. A triangle of given base and height, about the base.
15. A trapezoid about one of its parallel sides.
16. A thin circular plate, about a point on the circumference.
17. A thin plate bounded by two concentric circles, about the center.
18. An equilateral triangle, about its center.
19. An equilateral triangle, about one vertex.
20. $\rho = 2 \cos \theta$.
21. One loop of $\rho = \sin 2\,\theta$.
22. One loop of $\rho = \sin 3\,\theta$.
23. The cardioid $\rho = 1 - \cos \theta$.
24. The lemniscate $\rho^2 = \cos 2\,\theta$.

25. The spiral $\rho = \theta$, from $\theta = 0$ to π.

26. The spiral $\rho\theta = 1$, from $\theta = \pi/4$ to $\pi/2$.

27. $\rho = 1 + 2\cos\theta$, from $\theta = 0$ to π.

28. $\rho = \tan\theta$, from $\theta = 0$ to $45°$.

29. Calculate the moment of inertia of a cube about a corner.

30. Calculate the moment of inertia of a rectangular parallelopiped about a corner.

Calculate the moment of inertia about the origin of each of the solids bounded by the following surfaces and lying above the xy-plane. (See Exs. 2-11, p. 218.)

31. $z = x + y;\ y = 0;\ x = 0;\ x = 1;\ y = \sqrt{x}$.

32. $z = xy;\ y = x^2;\ y = 1$.

33. $z = x^2 + y;\ y = 0;\ x = 1;\ x = 3;\ y = x^2$.

34. $z = xy;\ y = 0;\ x = 1;\ x = 2;\ y = x^2 + 1$.

35. $z = x^2 - y^2;\ y = x^2;\ y = x$.

132. Average Value. Centroid. Let there be given a function $f(x, y)$ of two independent variables. At any point of the xy-plane, that is, for a given pair of values of x and y, this function will have a definite value.

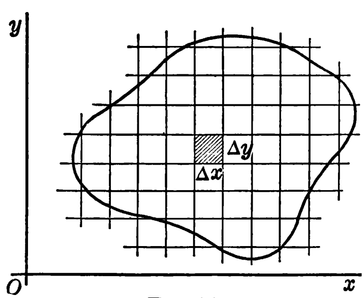

FIG. 64.

What will be the average value of $f(x, y)$ over a given region R? Divide the region into small squares, note the value of the function at some point of each square (for convenience at the corner nearest the origin). Let there be n complete squares in the region R, the fractional parts around the border being disregarded.

Then the average value of $f(x, y)$ at the corners of the squares will be

$$\frac{\text{Sum of values of } f(x, y)}{\text{Number of these values}} \text{ or } \frac{\Sigma f(x, y)}{n}.$$

Multiplying both sides by the element of area ΔA, and putting

$$n\Delta A = \Delta A + \Delta A + \Delta A + \cdots\cdots = \Sigma\, \Delta A,$$

we have
$$\frac{\Sigma f(x, y)\, \Delta A}{\Sigma\, \Delta A}$$

and the limit of this, as n increases and Δx and Δy decrease, is called the ***average value of $f(x, y)$ over the region R.*** Thus

(1) $$\textit{Av. Val. of } f(x,y) \textit{ over } R = \frac{\int f(x,y)\, dA}{\int dA} = \frac{\int\int f(x,y)\, dx\, dy}{\int\int dx\, dy}.$$

The denominator is simply the area of R; the limits are to be taken to cover the region R.

In polar coordinates, replace dA by $r\,d\theta\,dr$, and $f(x, y)$ by $F(r, \theta)$.

133. Centroid or Center of Gravity of an Area. The centroid, $(\bar{x}, \bar{y})$, of a plane area, as R in the above figure, is the point whose coordinates are the average values of the coordinates of the points of R, that is

(1) $$\bar{x} = \frac{\int x\, dA}{d\int A} \textit{ and } \bar{y} = \frac{\int y\, dA}{\int dA}.$$

For a material plate of uniform thickness and of mass k per unit area, the element of mass is $dM = k\,dA$ and its centroid is defined by

(2) $$\bar{x} = \frac{\int x\, dM}{\int dM}; \quad \bar{y} = \frac{\int y\, dM}{\int dM}$$

Here the ***density factor*** k may be a given function o₁ x and y; if k is constant it cancels out and we get the same result as for a plane area

134. Centroid of a Curved Arc. Similarly, ***the centroid of a curved arc*** is defined as the point whose coordinates are the average values of the coordinates of the points of the arc. Thus if AB is the arc, we divide it into n equal segments Δs, and note the values of x and y for some point of each Δs. The averages of these n values of x and y are, respectively,

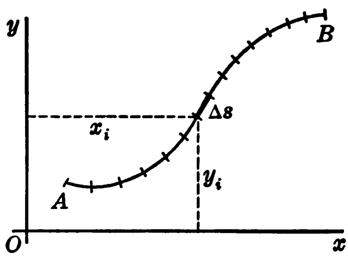

Fig. 65.

$$\frac{x_1 + x_2 + x_3 + \cdots + x_n}{n}; \quad \frac{y_1 + y_2 + y_3 + \cdots + y_n}{n}$$

Multiplying numerator and denominator by Δs and allowing n to increase, we have

$$(3) \qquad \bar{x} = \lim_{n\to\infty} \frac{\Sigma x \Delta s}{\Sigma \Delta s} = \frac{\int x\,ds}{\int ds}; \quad \bar{y} = \frac{\int y\,ds}{\int ds}.$$

135. Centroid of a Volume. Similarly, by dividing a volume into elements, and noting the coordinates (x, y, z) of a point of each element of volume, we obtain

$$(4) \qquad \bar{x} = \frac{\int x\,dV}{\int dV}, \quad \bar{y} = \frac{\int y\,dV}{\int dV}, \quad \bar{z} = \frac{\int z\,dV}{\int dV}.$$

In general we may take $dV = dx\,dy\,dz$, and so express (4) in terms of triple integrals. In numerous applications it is simpler, however, to take for dV a slice of the volume; thus in finding $\bar{x}$ cut the volume by a plane perpendicular to the x-axis, forming a section of area A_x; then take $dV = A_x\,dx$.

136. Definition of Centroid in Mechanics. From the standpoint of mechanics the centroid is defined in a different

manner that turns out to be equivalent to what we have done. Suppose the xy-plane to be horizontal and a wire bent into the form of any curve as AB to lie in this plane and to be balanced on a knife-edge MN, falling on the ordinate whose abscissa is $x = \bar{x}$. Divide the wire into elements of mass $\Delta m = k\,\Delta s$, multiply each Δm by its distance from the knife-edge and form the *sum of the moments* $\Sigma\, k(\bar{x} - x)\Delta s$. The limit of this sum must be zero if the wire is balanced, so we have $k \int (\bar{x} - x)\, ds = 0$. Hence $\int \bar{x}\, ds = \int x\, ds$, or, since $\bar{x}$ is a fixed value, $\bar{x} \int ds = \int x\, ds$. Hence $\bar{x} = \int x\, ds / \int ds$. Likewise we get $\bar{y}$ by supposing the wire to be balanced on a knife-edge parallel to the x-axis. The same considerations apply to a thin plate, except that Δs is replaced by ΔA. For a solid we pass planes parallel to the coordinate planes such that the sum of the moments of the elements of mass, *i.e.*, the products $(\bar{x} - x)\Delta m$, $(\bar{y} - y)\Delta m$, $(\bar{z} - z)\,\Delta m$, shall have the limit zero.

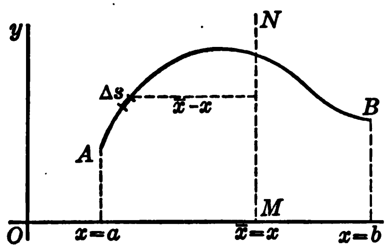

FIG. 66.

EXERCISES

Find the average value of each of the following functions, over the area under the curve $y = 1 - x^2$, from $x = 0$ to 1.

1. x. **2.** y. **3.** x^2. **4.** y^2.

5. $1/(1 + x)$. **6.** e^x.

Find the average value of each of the following functions in the volume bounded by the coordinate planes and the plane $x + y + z = 1$.

7. $f(x, y, z) = x$, or y, or z. **8.** $f(x, y, z) = xyz$.

9. $f(x, y, z) = xy$. **10.** $f(x, y, z) = x^2 + y^2 + z^2$.

11. Find the average ordinate of $y = \cos x$, from $x = 0$ to $\pi/2$.

12. Find the average ordinate of a semicircle.

13. Find the average distance of the points of the area of a circular quadrant from the center. (Use polar coordinates.)

14. Find the average density of a rod in which the density varies as the distance from one end.

Find the centroids of the following figures:

15. Of the segment of the parabola $y^2 = 4\,ax$, from $x = 0$ to h.

16. Of a semicircle.

17. Of the first quadrant of an ellipse.

18. Of the area under $y = \cos x$, from $x = 0$ to $\pi/2$.

19. Of a right circular cone.

20. Of a regular pyramid. (Use sections parallel to the base.)

21. Of a semiellipsoid of revolution.

22. Of a circular quadrantal arc.

23. Of a circular arc of angle $2\,\alpha$.

24. Of the arc of $x^{2/3} + y^{2/3} = a^{2/3}$, in the first quadrant.

25. Of the arc of $y = (e^x + e^{-x})/2$, from $x = 0$ to 1.

Find the centroids $(\bar{x}, \bar{y})$ for the areas bounded by the following curves:

26. $y = x^2$ and $y = \sqrt{x}$.

27. $y = x^2$ and $y = x^3$.

28. $x^2 + y^2 = 12$ and $y = x^2$.

29. $y^2 = x$ and $y = 1 - x$.

30. $y = 2\,x$, $y = 0$, and $y = 1 - x$.

31. $\rho = 2 \cos \theta$.

32. One loop of $\rho = \sin 2\,\theta$.

33. The cardioid, $\rho = 1 - \cos \theta$.

34. The lemniscate, $\rho^2 = \cos 2\,\theta$.

35. The spiral, $\rho = \theta$, from $\theta = 0$ to π.

36. $\rho = 1 + 2 \cos \theta$, from $\theta = 0$ to π.

GENERAL REVIEW EXERCISES

Find the areas bounded by each of the following curves, or the part specified:

1. $\rho = a \cos \theta + b$.

2. $\rho = a \cos 3\theta$.

3. $y^2 (a - x) = x^3$ [cissoid]; to its asymptote $x = a$.

4. $y^2 = x^2 (4 - x)$: the loop.

Find the volume generated by revolving each of the following curves about the line specified:

5. $y = 5x/(2 + 3x)$; about $y = 0$; $x = 0$ to $x = 1$.

6. $2x^2 + 5y^2 = 8$; about $y = 0$; total solid.

7. $y = b \sin (x/a)$; about $y = 0$; $x = 0$ to $x = \pi$.

8. $y = a \cosh (x/a)$; about $y = 0$; $x = 0$ to $x = a$.

9. $(x - a)^2 + y^2 = r^2$; about $x = 0$; total solid.

10. The cycloid; about base; one arch.

11. The cycloid; about tangent at maximum; one arch.

12. The tractrix; about asymptote; total.

13. $x = a \cos^3 t$, $y = a \sin^3 t$; about $y = 0$; total solid.

Find the area, its centroid, and its moment of inertia about the origin, for each of the following curves, between the limits indicated:

14. $y = a(1 - x^2/b^2)$; 1st quadrant.

15. $y = x/(1 + x^2)$; $x = 0$ to $x = 1$.

16. The sine curve; one arch.

17. The cycloid; one arch.

18. $x^{2/3} + y^{2/3} = a^{2/3}$ [*or* $x = a \cos^3 t$, $y = a \sin^3 t$]; first quadrant.

19. Between the two circles $\rho = a \cos \theta$ and $\rho = b \cos \theta$; $b > a$.

20. $x = 2a \sin^2 \phi$, $y = 2a \sin^2 \phi \tan \phi$; between the curve and its asymptote.

Find the centroid of each of the following frusta:

21. Of the paraboloid $x^2 + y^2 = 4az$ by the plane $z = c$.

22. Of a hemisphere.

23. Of the upper half of the ellipsoid of revolution

$$4x^2 + 4y^2 + 9z^2 = 36.$$

24. Of the upper half of the ellipsoid $x^2 + 4y^2 + 9z^2 = 36$.

25. Of the solid of revolution formed by revolving half of one arch of a cycloid about its base.

26. Obtain a formula for the volume of a spherical segment of height h.

27. Show that the volume of an ellipsoid of three unequal semiaxes, a, b, c, is $4\pi abc/3$.

28. Show that the volume bounded by the cylinder $x^2 + y^2 = ax$, the paraboloid $x^2 + y^2 = bz$, and the xy-plane is $(3/32)(\pi a^4/b)$.

29. Find the volume common to a sphere and a cone whose vertex lies on the surface and whose axis coincides with a diameter of the sphere.

Find the lengths of the arcs of each of the following curves, between the points specified:

30. $y = \log x$; $x = a$ to $x = b$.

31. $e^y \cos x = 1$; $x = 0$ to $x = x$.

32. $x = t^2$, $y = 2at$ (or $y^2 = 4a^2x$); $t = t_1$ to $t = t_2$.

33. One arch of a cycloid.

34. $\rho = a(1 + \cos\theta)$ [cardioid]; total length.

35. Calculate the moment of inertia I for a right circular cone about its axis. *Ans.* (3/10) mass · square of radius.

36. Calculate the moment of inertia and the radius of gyration for the rim of a flywheel about its axis, the inner and outer radii being R_1, R_2.

37. The moment of inertia of an ellipsoid about any one of its axes is (1/5) (mass) (sum of the squares of the other two semi-axes).

38. Calculate the moment of inertia for a spherical segment about the axis of the segment.

39. Show that, for any body, $2I_0 = I_x + I_y + I_z$, where I_0, I_x, I_y, I_z denote respectively its moments of inertia about a point and three rectangular axes through that point.

40. Show that for any figure in the xy-plane, $I_z = I_x + I_y$, where I_x, I_y, I_z denote its moments of inertia about the three coordinate axes respectively.

41. Show that the total pressure on a rectangle of height h feet and width b feet immersed vertically in water so that its upper edge is a feet below the surface and parallel to it, is $62.4\,bh\,(a + h/2)$. Show that the depth of the center of pressure is at $(6\,a^2 + 6\,ah + 2\,h^2)/(6\,a + 3\,h)$.

42. Show that the total pressure on a circle of radius r, immersed vertically in water so that its center is at a depth $a + r$, is $62.4\,\pi r^2\,(a + r)$. Show that the depth of the center of pressure is $a + r + r^2/(4\,r + 4\,a)$.

43. Show that the total pressure on a semicircle, immersed vertically in water with its bounding diameter in the surface, is $41.6\,r^3$. Show that the depth of the center of pressure is $3\,\pi r/16$.

44. Calculate the water pressure to within 1 % on a circular disk 10 ft. in diameter, if its plane is vertical and center 10 feet below the surface.

45. Show that if a triangle is immersed in a liquid with its plane vertical and one side in the surface, the center of pressure is at the middle of the median drawn to the lowest vertex.

46. Show that if a triangle is immersed in a liquid with its plane vertical and one vertex in the surface, the opposite side being parallel to the surface, the center of pressure divides the median drawn from the highest vertex in the ratio 3: 1.

47. Calculate the mean ordinate of one arch of a sine-curve. The mean square ordinate. [Effective E. M. F. in an alternating electric current.]

48. Calculate the average distance of the points of a square from one corner.

49. What is the average distance of the points of a semicircular arc from the bounding diameter?

50. When a liquid flows through a pipe of radius R, the speed of flow at a distance r from the center is proportional to $R^2 - r^2$. What is the average speed over a cross section? What is the quantity of flow per unit time across any section?

51. The kinetic energy E of a moving mass is $\lim \sum \Delta m \cdot v^2/2$, where Δm is the element of mass moving with speed v. Show that for a disk rotating with angular speed ω, $E = \omega^2 I/2$. Calculate E for a solid car wheel of steel, 30 in. in diameter and 4 in. thick when the car is going 20 m./hr.

52. Show that the kinetic energy E of a sphere rotating about a diameter with angular speed ω is $(1/5)(\text{mass})\, r^2\omega^2$.

53. Calculate the kinetic energy in foot-pounds of the rim of a fly-wheel whose inner diameter is 3 ft., cross section a square 6 in. on a side, if its angular speed is 100 R. P. M. and its density is 7.

54. The x-component of the attraction between two particles m and m', separated by a distance r, is $(k \cdot m \cdot m'/r^2) \cos (r, x)$ where $\cos (r, x)$ denotes the cosine of the angle between r and the x-axis. Hence the x-component of the attraction between two elementary parts of two solids M and M' is $(k \cdot \Delta M \cdot \Delta M'/r^2) \cos(r, x)$. Show that the total attraction between the two solids is expressible by a six-fold integral.

55. A uniform rod attracts an external particle m. Calculate the components of the attraction parallel and perpendicular to the rod; the resultant attraction and its direction.

[HINT. Let ΔM be an element of the rod; then $\Delta F = k\,\Delta M \cdot m/r^2$ is the force due to ΔM acting on m, r being the distance from ΔM to m; then the components of ΔF are $\Delta X = \Delta F \cos \alpha$ and $\Delta Y = \Delta F \sin \alpha$, where α is the angle between r and the rod. Hence

$$X = \int \frac{kmdM}{r^2} \cos \alpha, \text{ and } Y = \int \frac{kmdM}{r^2} \sin \alpha.]$$

56. Show that in spherical coordinates, (r, θ, ϕ), the volume of a solid is given by an integral of the form

$$\iiint r^2 \cos \phi \, d\phi \, d\theta \, dr.$$

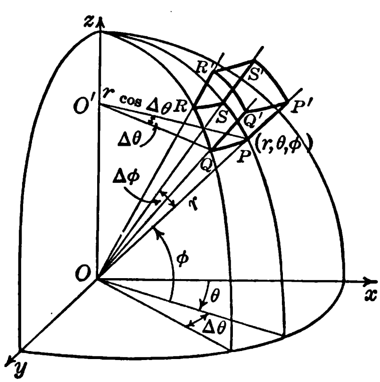

FIG. 67.

[HINT. Let P be a point on a sphere of radius r, the longitude of P being θ and its latitude ϕ. It is usual to let the xy-section of the sphere be the equator and the xz-section the prime meridian. Then P is the point (r, θ, ϕ). PS and QR are two adjacent meridians and PQ, SR are two adjacent parallels. Then

$Q = (r, \theta + \Delta\theta, \phi)$, $R = (r, \theta + \Delta\theta, \phi + \Delta\phi)$, $S = (r, \theta, \phi + \Delta\phi)$. Also $PS = r\,\Delta\phi$ and $PQ = O'P \cdot \Delta\theta = r \cos \phi\, \Delta\theta$.

Suppose r to increase to $r + \Delta r$ so that P, Q, R, S move out to P', Q', R', S' respectively. In this way is formed the element of volume in spherical coordinates. Its approximate volume is

$$PS \cdot PQ \cdot PP' = r\,\Delta\theta \cdot r\cos\phi\,\Delta\theta \cdot \Delta r = r^2\cos\phi\,\Delta\theta\,\Delta\phi\,\Delta r.]$$

57. Calculate the volume of a sphere, using spherical coordinates.

58. Calculate the volume cut from a cone of angle 2α by two concentric spheres with centers at the vertex of the cone.

59. Show that, in cylindrical coordinates (r, θ, z), the volume of a solid is given by an integral of the form

$$\int\int\int r\,d\theta\,dr\,dz.$$

Here r denotes distance from the z-axis.

[HINT. The coordinates of $P = (r, \theta, z)$ are $OM = r$, $xOM = \theta$, $MP = z$.]

$$Q = (r, \theta + \Delta\theta, z);$$
$$R = (r, \theta + \Delta\theta, z + \Delta z);$$
$$S = (r, \theta, z + \Delta z).$$

Increase r to $r + \Delta r$, so that we have an element of volume whose approximate volume is

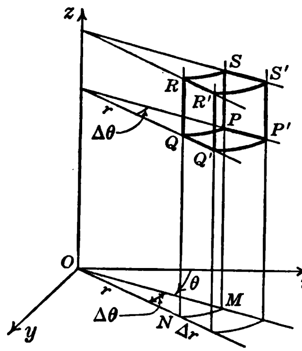

FIG. 68.

$$PQ \cdot PS \cdot PP' = r\,\Delta\theta \cdot \Delta z \cdot \Delta r.$$

60. Calculate the volume of a sphere using cylindrical coordinates.

61. Determine the part of the cylinder $r = \sin 2\theta$ which lies between the planes $z = 0$ and $z = y$.

62. Determine the part of the cylinder $r = \sin 2\theta$ which lies between the planes $z = 0$ and $x + y + z = \sqrt{2}$.

CHAPTER XV

EMPIRICAL CURVES — INCREMENTS — INTEGRATING DEVICES

137. Empirical Curves. Some of the methods used in science to draw the curves which represent simultaneous values of two related quantities and to obtain an equation which represents that relation approximately are given in Analytic Geometry. Usually the pairs of corresponding values are plotted on squared paper first; in all that follows it is assumed that this has been done in each case.

138. Polynomial Approximations. It is advantageous to have equations which are as simple as possible. From experimental results, it is not to be expected that absolutely precise equations can be found, and the attempt is made to get an equation of simple form which *approximately* represents the facts, in so far as the facts themselves are known. One simple kind of function which often does approximately express the facts is a ***polynomial:***

$$(1) \qquad y = a + bx + cx^2 + dx^3 + \cdots + kx^n.$$

139. Logarithmic Plotting. The preceding forms of equations may not represent the facts very well unless a large number of terms (1), § 138, are used.

If the first graph resembles one of the curves $y = x^2$, $y = x^3$, $y = x^4$, etc., or $y = x^{1/2}$, $y = x^{1/3}$, etc., or $y = 1/x$, $y = 1/x^2$, etc., it is advantageous to plot the ***common logarithms of the quantities measured*** instead of the actual values of those quantities.

If x and y represent the quantities measured, and $u = \log_{10} x$, $v = \log_{10} y$ are their common logarithms, the values of u and v may lie very nearly on a straight line,

$$(1) \qquad v = a + bu,$$

where a and b are found by drawing the straight line which on the whole seems to approximate best to the points (u, v) and measuring its slope, b, and the v-intercept, a. Then from (1), since $u = \log_{10} x$, $v = \log_{10} y$,

$$(2) \quad \log_{10} y = a + b \log_{10} x = \log_{10} k + \log_{10} x^b = \log_{10} (kx^b),$$

where $\log_{10} k = a$; hence

$$(3) \qquad y = kx^b.$$

This form of equation is very convenient for computation and is used in practice very extensively wherever the logarithmic graph is approximately a straight line.* This work applies equally well for negative and fractional values of b.

In many cases where the process just described fails, it is sometimes advantageous to assume that the equation has the form $(y - B) = k(x - A)^n$ which evidently has a horizontal tangent at the point (A, B) if $n > 1$, or a vertical tangent if $n < 1$. If the first graph (in x and y) shows such a vertical or horizontal tangent, that point (A, B) may be

* To avoid the trouble of looking up the logarithms, a special paper usually described in Analytic Geometry may be purchased which is ruled with logarithmic intervals. No particular explanation of this paper is necessary except to say that it is so made that if the values of x and y are plotted directly, the graph is identical with that described above. To secure this result the successive rulings are drawn at distances proportional to log 1 (=0), log 2, log 3, $\cdots$ from one corner, both horizontally and vertically.

Explanations and numerous figures are to be found in many books; see, *e.g.*, Kent, "Mechanical Engineers' Pocket Book" (Wiley, 1910), p. 85; Trautwine, "Civil Engineers' Pocket Book" (Wiley), (Chapter on Hydraulics).

selected as a new origin, and the values $x' = x - A$ and $y' = x - B$ should be used; thus we would plot the values of

$$u = \log_{10} x' = \log_{10}(x - A), \quad v = \log_{10} y' = \log_{10}(y - B),$$

in the manner described above. The values of A and B are found from the first graph (in x and y); the values of k and n are found from the logarithmic graph as above.

140. Semi-logarithmic Plotting. Variations of this process of § 139 are illustrated in the exercises below. In particular, if the quantities are supposed to follow a *compound interest law*, $y = ke^{bx}$, it is advantageous to take logarithms of both sides:

$$\log_{10} y = \log_{10} k + bx \log_{10} e,$$

and then plot $u = x$, $v = \log_{10} y$; if the facts are approximately represented by any compound interest law, the experimental graph (in u and v) should coincide (approximately) with the straight line

$$v = A + Bu,$$

where $A = \log_{10} k$ and $B = b \log_{10} e$. After A and B have been measured, k and b [$= B \log_e 10 = 2.303\ B$] can be found.

EXERCISES

1. Find the equation of a straight line through the points $(-1, 3)$ and $(2, 5)$; through $(2, -3)$ and $(4, 5)$.

2. Plot the data of Exercises 37-42, page 58; draw a straight line as closely as possible through all the points without giving preference to any of them; determine the equation from this graph; compare with former results.

Plot each of the following curves logarithmically, — either by plotting $\log_{10} x$ and $\log_{10} y$, or else by using logarithmic paper:

3. $y = 2x^3$.
4. $y = 3x^{1/2}$.
5. $y = .4x^{3.2}$.
6. $y = 3x^{-2}$.
7. $y = 5.7x^{.6}$.
8. $y = -1.4x^{2.4}$.

In each of the following tables, the quantities are the results of actual experiments; the two variables are supposed theoretically to be connected by an equation of the form $y = kx^n$. Draw a logarithmic graph and determine k and n, approximately:

9. [Steam pressure; v = volume, p = pressure.] [Saxelby.]

v	2	4	6	8	10
p	68.7	31.3	19.8	14.3	11.3

10. [Gas engine mixture; notation as above.] [Gibson.]

v	3.54	4.13	4.73	5.35	5.94	6.55	7.14	7.73	8.04
p	141.3	115	95	81.4	71.2	63.5	54.6	50.7	45

11. [Head of water h, and time t of discharge of a given amount.] [Gibson.]

h	0.043	0.057	0.077	0.095	0.100
t	1260	540	275	170	138

12. [Heat conduction, asbestos; θ = temperature (F.), C = coefficient of conductivity.] [Kent.]

θ	32°	212°	392°	572°	752°	1112°
C	1.048	1.346	1.451	1.499	1.548	1.644

13. [Track records: d = distance, t = record time (intercollegiate).]

d	100 yd.	220 yd.	440 yd.	880 yd.	1 mi.	2 mi.
t	0:09$\frac{4}{5}$	0:21$\frac{1}{5}$	0:48$\frac{4}{5}$	1:56	4:17$\frac{4}{5}$	9:27$\frac{3}{5}$

[NOTE. See Kennelly, Fatigue, etc., *Proc. Amer. Acad. Sc.* XLII, No. 15, Dec. 1906; and *Popular Science Monthly*, Nov. 1908.]

Plot the following curves, using logarithmic values of one quantity and natural values of the other:

14. $y = e^x$. **15.** $y = 10\,e^{3x}$. **16.** $y = 4\,e^{-x}$. **17.** $y = .1\,e^{-x/3}$.

Discover a formula of the type $y = ke^{ax}$ for each of the following sets of data:

18.	x:	.2	.4	.6	.8	1.0
	y:	4.5	6.6	9.9	15.0	22.2
19.	x:	.6	1.2	1.8	2.4	3.0
	y:	1.5	2.2	3.3	5.0	7.4
20.	x:	.31	.63	.94	1.26	1.57
	y:	2.44	2.98	3.64	4.46	5.44
21.	x:	.2	.8	2.0	4.0	
	y:	8.2	4.5	1.3	0.2	
22.	x:	.63	1.26	2.51	3.77	5.03
	y:	4.02	2.70	1.20	0.54	0.24
23.	x:	1	2	3	4	5
	y:	3.26	2.68	2.16	1.80	1.46

24. A is the amplitude of vibration of a long pendulum, t is the time since it was set swinging. Show that they are connected by a law of the form $A = ke^{-nt}$.

A in. =	10	4.97	2.47	1.22	.61	.30	.14
t min. =	0	1	2	3	4	5	6

141. Method of Increments. A method adapted to the case where (1) of § 138 has the form

$$(1)\qquad y = a + bx + cx^2,$$

is as follows. From two pairs of values of x and y, say (x, y) and $(x + \Delta x, y + \Delta y)$ given by experiment, we should have

$$(2)\quad y = a + bx + cx^2, y + \Delta y = a + b\,(x + \Delta x) + c\,(x + \Delta x)^2,$$

whence

$$(3)\qquad \Delta y = b\,\Delta x + 2\,cx\,\Delta x + c\,\overline{\Delta x}^2.$$

If Δx is constant, *i.e.* if points are selected at equal x-intervals on the crudely sketched curve drawn through the experimental points, we might write

$$(4) \qquad Y = \Delta y = (bh + ch^2) + 2\,ch \cdot x = A + Bx$$

where $h = \Delta x$. If we should actually plot this equation, $Y = A + Bx$, we would get (approximately) a straight line. Now $\Delta y = Y$ is the difference of two values of y; it can be found for each of the values of x selected above, and the (approximate) straight line can be drawn, so that A and B can be measured.

We may repeat the preceding process; from (4) we obtain, as above,

$$(5) \qquad \Delta Y = B\Delta x = 2\,ch^2, \quad (h = \Delta x),$$

whence ΔY is *constant* if h was taken constant. Now ΔY is the difference between two values of Y; that is, ΔY is the difference between two values of Δy:

$$\Delta Y = \Delta\,(\Delta y) = \Delta^2 y,$$

and for that reason is called a ***second difference,*** or a ***second increment.*** If the second differences are reasonably constant, we conclude that an equation of the form (1) will reasonably represent the facts and we find c directly by solving equation (5).

EXAMPLE 1. With a certain crane it is found that the forces f measured in pounds which will just overcome a weight w are

f	8.5	12.8	17.0	21.4	25.6	29.9	34.2	38.5
w	100	200	300	400	500	600	700	800

What is the law connecting force with the weight that it just overcomes? [PERRY.]

Plotting the values of f and w, it appears that the points are very

nearly on a straight line $f = a + bw$. If they were on a straight line, $\Delta f/\Delta w$ would be constant and equal to $df/dw = b$. As a matter of fact, for each increase of weight, $\Delta f/\Delta w$ varies only from .042 to .044, its average value being $30/700 = .0429$ Taking this value for b, one gets for the equation of the line, and hence for the relation between force and weight:

$$f = 4.21 + .0429\, w, \quad 4.21 = 8.5 - 100 \times .0429$$

Here 4.21 appears to be the force needed to start the crane if no load were to be lifted.

EXAMPLE 2. If θ is the melting point (Centigrade) of an alloy of lead and zinc containing $x\%$ of lead, it is found that

x = % lead	40	50	60	70	80	90
θ = melting point	186	205	226	250	276	304

Plotting the points (x, θ) will show them not to lie in a straight line as is also shown by the difference $\Delta\theta$. But $\Delta(\Delta\theta)$ or $\Delta^2\theta$ does run uniformly. Therefore one tries a quadratic function of x for θ, that is

$$\theta = a + bx + cx^2.$$

It is evident that $\quad \Delta\theta = 10\,b + c\,(20\,x + 100),$

and $\quad \Delta^2\,\theta = 200\,c.$

The average value of $\Delta^2\,\theta$ is 2.25 Hence $c = .01125$ If we subtract cx^2 from θ, we find $\theta - cx^2 = a + bx$. These values can be calculated from the data and from $c = .01125$; they will be found to lie on a straight line; hence a and b can be found by any one of several preceding methods. The student will readily obtain, approximately,

$$\theta = 133 + .875\,x + .01125\,x^2,$$

a formula which represents reasonably the melting point of any zinc-lead alloy. [SAXELBY.]

EXERCISES

1. Express $f(x)$ as a quadratic function of x, when

x:	0	0.5	1.0	1.5	2.0	2.5	3.0
$f(x)$:	2.5	1.9	1.6	1.5	1.7	2.1	2.8

2. Express $f(x)$ as a cubic function of x, when

x:	0	.02	.04	.06	.08	.10	.12	.14
$f(x)$:	0	.020	.042	.064	.087	.111	.136	.163

3. Express $\phi(m)$ as a cubic in m, when

m:	.01	.02	.03	.04	.05	.06	.07	.08
$\phi(m)$:	.00010	.00041	.00093	.00166	.00260	.00385	.00530	.00690

4. The specific heat S of water, at $\theta°$ C., is

θ:	0	5	10	15	20	25	30
S:	1.0066	1.0038	1.0015	1.0000	0.9995	1.0000	1.002

Express S in terms of θ.

5. Determine a relation between the vapor pressure P of mercury, and the temperature θ C., from the data below:

θ:	60	90	120	150	180	210	240
P:	.03	.16	.78	2.93	9.23	25.12	58.8

6. The resistance R, in ohms per 1000 feet, of copper wire of diameter D mils, is

D:	289	182	102	57	32	18	10
R:	.126	.317	1.010	3.234	10.26	32.8	105.1

Find a relation between R and D.

7. The Brown and Sharpe gauge numbers N of wire of diameter D mils, are

N:	1	5	10	15	20	25	30
D:	289	182	102	57	32	18	10.

Express D in terms of N.

8. Find a relation between the speed S of a train in kilometers per hour, and the horse-power (H. P.) of the engine from the data below:

H. P.:	550	650	750	850
S:	26	35	52	70.

9. The energy consumed in overcoming molecular friction when iron is magnetized and demagnetized (hysteresis, H, — measured in watts per cycle per liter of iron) is given below in terms of the strength of the magnetic field (B, — measured in lines per square centimeter). What is the relation between them?

B:	2000	4000	6000	8000	10000	14000	16000	18000
H:	.022	.048	.085	.138	.185	.320	.400	.475

10. Proceed as in Ex. 15, for cobalt, the hysteresis loss H being now measured in ergs per cycle per second:

B:	900	2350	3100	4100	4600	5200	5850	6500
H:	450	2450	3950	6300	7400	8950	10950	13250.

The table below contains some data on the comparison of a tungsten lamp with a tantalum lamp. The voltage or electrical pressure V, is in volts, the resistance R, in ohms, the current consumed in watts per candle power; C denotes candle power, and W watts per candle power.

11. TUNGSTEN **12.** TANTALUM

Voltage V	C. P. C	Watts per C. P. W	Resistance R	C. P. C	Watts per C. P. W	Resistance R
80	14	2.51	166	5	3.80	260
90	24	1.83	173	10	2.85	265
100	36	1.49	182	18	2.05	275
110	52	1.23	190	25	1.65	283
120	71	1.10	197	38	1.35	290
130	95	0.96	202	50	1.15	300
140	128	0.83	210	62	0.95	308
150	160	0.76	216	78	0.85	315
160	196	0.58	222	100	0.75	323
170	230	0.52	227	122	0.70	327
180	270	0.50	232	156	0.70	332
190	312	0.48	238	190	0.60	340
200	340	0.47	242	235	0.55	345

For each lamp, express each of the quantities C, W, R, in terms of V.

142. Integrating Devices. It is important in many practical cases to know approximately the areas of given closed curves. Thus the volume of a ship is found by finding the areas of cross sections at small intervals. Besides the methods described above, the following devices are employed:

A. Counting squares on cross-section paper.

B. Weighing the figures cut from a heavy cardboard of uniform known weight per square inch.

C. *Integraphs*. These are machines which draw the integral curve mechanically; from it values of the area may be read off as heights.

The simplest such machine is that invented by ABDANK-ABAKANOWICZ. A heavy carriage $CDEF$ on large rough rollers, R, R' is placed on the paper so that CE is parallel to the y-axis.

Two sliders S and S' move on the parallel sides DF and CE; to S is attached a pointer P which follows the curve $y = f(x)$. A grooved rod AB slides over a pivot at A, which lies on the x-axis, and is fastened by pivot B to the slider S. A parallelogram mechanism forces a sharp wheel W attached to the slider S' to remain parallel to AB. A marker Q draws a new curve $i = \phi(x)$, which obviously has a tangent parallel to W, that is, to AB. If AB makes an angle α with Ox, $\tan \alpha$ is the slope of the new curve; but $\tan \alpha$ is the height of S divided by the fixed horizontal distance h between A and B:

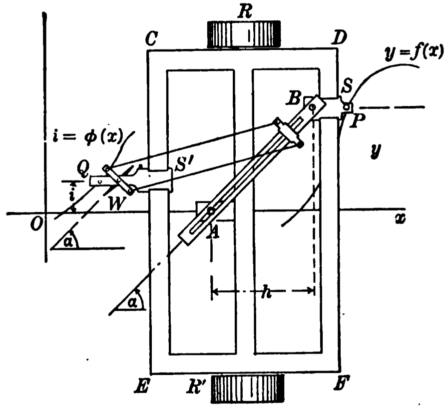

FIG. 69.

$$\frac{d\,\phi(x)}{dx} = \tan \alpha = \frac{\text{height of } S}{h} = \frac{f(x)}{h},$$

whence
$$i - i_0 = \frac{1}{h}\int_{x=a}^{x=x} f(x)\,dx;$$

where a is the value of x at P when the machine starts, and i_0 denotes the vertical height of the new curve at the corresponding point.

D. Polar Planimeters. — There are machines which read off the area directly (for any smooth closed curve of simple shape) on a dial attached to a rolling wheel.

The simplest such machine is that invented by AMSLER.

Let us first suppose that a moving rod ab of length l always remains perpendicular to the path described by its center C. The path of C may be regarded as the limit of an inscribed polygon, and the area swept over by the rod may be thought of as the limit of the sum of small

quadrilaterals, the area ΔA of each of which is $l\Delta p$, approximately, where Δp is the length of the corresponding side of the polygon inscribed in the path of C. Hence the total area A swept over by the rod is evidently lp, where p is the total length of the path of C.

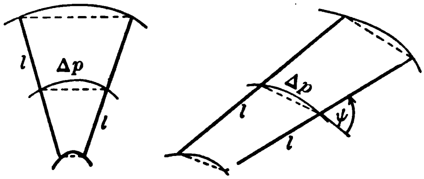

Fig. 70.

But if the rod does not remain perpendicular to the path of C during the motion, and if ψ is the angle between the rod and that path, the area ΔA becomes $l \sin \psi \cdot \Delta p$, approximately. The expression $\sin \psi \cdot \Delta p$ may be thought of as the component of Δp in a direction perpendicular to the rod. Calling this component Δs, we have $\Delta A = l\Delta s$, approximately; and the total area A swept over by the rod is precisely $\lim \Sigma \Delta A = \lim \Sigma l \Delta s = \int l\, ds = l \int ds = ls$, where $s = \int ds$ is the total motion of C in a direction perpendicular to the rod.

The quantity $s = \int ds$ can be measured mechanically by means of a wheel of which the rod is the axle, attached to the rod at C; for if θ is the total angle through which the wheel turns during the motion, $s = r\theta$, where r is the radius of the wheel, and θ is measured in radians. Hence $A = ls = lr\theta$; the value of θ is read off from a dial attached to the wheel; l and r are known lengths.

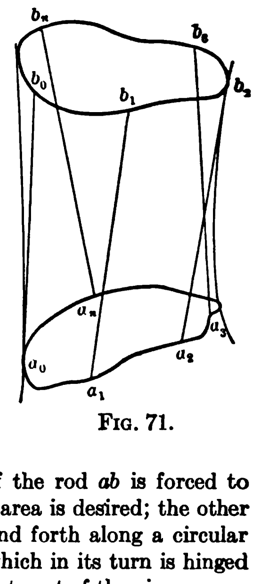

Fig. 71.

In *Amsler's polar planimeter*, one end b of the rod ab is forced to trace once around a given closed curve whose area is desired; the other end a is mechanically forced to move back and forth along a circular arc by being hinged at a to another rod Oa, which in its turn is hinged to a heavy metal block at O. As b describes that part of the given curve which lies farthest from O, the rod ab sweeps over an area between the circular arc traced by a and the outer part of the given curve; as b describes the part of the curve nearest to O, ab sweeps back over a portion of the area covered before, between the circle and the inner part of the given curve. This latter area does not count in the final total, since it has been swept over twice in opposite directions. Hence

the quantity $A = lr\theta$, given by the reading of the dial on the machine, is precisely the desired area of the given closed curve, which has been swept over just once by the moving rod ab.

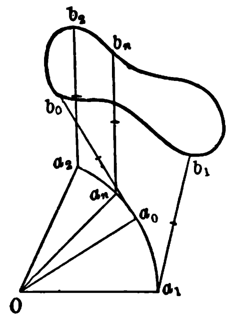

FIG. 72.

In practicing with such a machine, begin with curves of known area. The machine is useful not only in finding areas of irregular curves whose equations are not known, but also in checking integrations performed by the standard methods, and in giving at least approximate values for integrals whose evaluation is difficult or impossible.

For further information on integrating devices, see: Abdank-Abakanowicz, *Les intégraphes* (Paris, Gauthier-Villars); Henrici, *Report on Planimeters* (British Assoc. 1894, pp. 496–523); Shaw, *Mechanical Integrators* (Proc. Inst. Civ. Engs. 1885, pp. 75–143); Encyklopädie der Math. Wiss., Vol. II. Catalogues of dealers in instruments also contain much really valuable information.

EXERCISES

1. Construct a figure of each of the types mentioned below, with dimensions selected at random, and find their areas approximately by counting squares; by Simpson's rule; by the planimeter, if one is available. (1) A right triangle; (2) An equilateral triangle; (3) A circle; (4) An ellipse. (Draw it with a thread and two pins.) (5) An arch of a sine curve; (6) An arch of a cycloid.

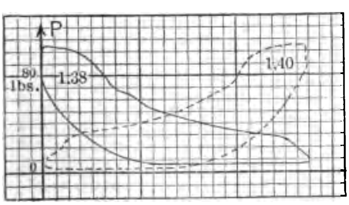

FIG. 73 (*a*).

2. The figures below are reproductions of indicator cards, taken from three different types of engines. The dotted curves are entirely separate from the full lines. The *average pressure* on the piston is the area of one of these curves divided by the length of stroke. Find this value in each case, where the stroke is 12 in. in the first figure, and 8 in. in each of the others. (Unit of area = 1 large square.)

[NOTE. The *work done* is precisely the area in question, on a proper scale, since the work is the average pressure times the length of stroke.]

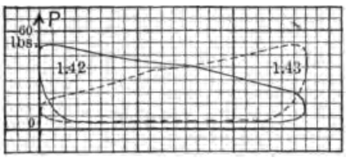

FIG. 73 (*b*).

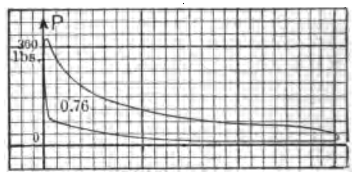

FIG. 73 (*c*).

CHAPTER XVI

LAW OF THE MEAN — TAYLOR'S FORMULA — SERIES

143. Rolle's Theorem. Let us consider a curve

$$y = f(x),$$

where $f(x)$ is single-valued and continuous, and where the curve has at every point a tangent that is not vertical. If such a curve cuts the x-axis twice, at $x = a$ and $x = b$, it surely either has a maximum or a minimum at at least one point $x = c$ between a and b. It was shown in § 33, p. 54, that the derivative at c is zero:

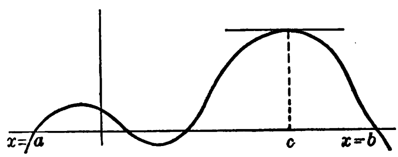

FIG. 74.

[A] If $f(a) = f(b) = 0$, then $\left[\dfrac{df(x)}{dx}\right]_{x=c} = 0$, $(a < c < b)$;

this fact is known as ***Rolle's Theorem.***

144. The Law of the Mean. Rolle's Theorem is quite evident geometrically in the form: *An arc of a simple smooth curve cut off by the x-axis has at least one horizontal tangent.* The precise nature of the necessary restrictions is given in § 129.

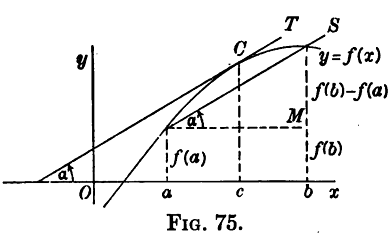

FIG. 75.

Another similar statement, which is true under the same restrictions and is equally obvious geometrically, is: *An arc of a simple smooth curve cut off by any secant has at least one tangent parallel to that secant.*

If the curve is $y = f(x)$, and if the secant S cuts it at points P:$[a, f(a)]$ and Q:$[b, f(b)]$, the slope of S is

$$\Delta y \div \Delta x = [f(b) - f(a)] \div (b - a).$$

The slope of the tangent CT at $x = c$ is equal to this:

$$[B] \quad \left.\frac{dy}{dx}\right]_{x=c} = \left.\frac{df(x)}{dx}\right]_{x=c} = \frac{f(b) - f(a)}{b - a} = \frac{\Delta y}{\Delta x}, \qquad (a < c < b).$$

This statement is called the ***law of the mean*** or the ***theorem of finite differences.***

It is easy to prove this statement algebraically from Rolle's Theorem. For if we subtract the height of the secant S from the height of the curve, we get a new curve whose height is:

$$D(x) = f(x) - \left[\frac{f(b) - f(a)}{b - a}(x - a) + f(a)\right].$$

Now $D(x)$ is zero when $x = a$ and when $x = b$. It follows by § 143 that $d\,D(x)/dx = 0$ at $x = c$, $(a < c < b)$:

$$\left.\frac{d\,D(x)}{dx}\right]_{x=c} = \left(\frac{df(x)}{dx} - \left[\frac{f(b) - f(a)}{b - a}\right]\right)_{x=c} = 0, \quad (a < c < b),$$

which is nothing but a restatement of $[B]$.

145. Increments. The law of the mean is used to determine increments approximately, and to evaluate small errors.

If $y = f(x)$ is a given function, we have, by § 144,

$$[B] \qquad \Delta y = \left.\frac{dy}{dx}\right]_{x=c} \cdot \Delta x.$$

In practice this law is used to estimate the extreme limit of errors, that is, the extreme limit of the numerical value of Δy. It is evident that

$$[B^*] \qquad |\Delta y| \leqq M_1 \cdot |\Delta x|,$$

where M_1 is the maximum of the numerical value of dy/dx between a and $a + \Delta x$. When Δx is very small, the slope dy/dx

is practically constant from a to $a + \Delta x$ in most instances, and M_1 is practically the same as the value of dy/dx at any point between a and $a + \Delta x$.

EXAMPLE 1. To find the correct increments in a five-place table of logarithms.

The usual logarithm table contains values of $L = \log_{10} N$ at intervals of size $\Delta N = .001$. Hence

$$\Delta L = \left[\frac{d \log_{10} N}{dN}\right]_{N=c} (.001) = \left[\frac{.001}{N} \log_{10} e\right]_{N=c} = \left[\frac{.00043}{N}\right]_{N=c},$$

where $N < c < N + .001$.

Logarithms are ordinarily given from $N = 1$ to $N = 10$. Hence ΔL will vary from .00043 at the beginning of the table to .00004 at the end of the table. This agrees with the "differences" column in an ordinary logarithm table.

EXAMPLE 2. The reading of a certain galvanometer is proportional to the tangent of the angle through which the magnetic needle swings. Find the effect of an error in reading the angle on the computed value of the electric current measured. We have

$$C = k \tan \theta,$$

where C is the current and θ the angle reading. Hence the error E_C in the computed current is

$$E_C = \Delta C = \frac{kd \tan \theta}{d\theta}\Bigg]_{\theta=\alpha} \Delta\theta = k\,\Delta\theta \cdot \sec^2 \alpha, \qquad (\theta \lesseqgtr \alpha \lesseqgtr \theta \pm \Delta\theta),$$

where E_C is the error in the computed value of the current, and $\Delta\theta$ is the error made in reading the angle θ. Since $\Delta\theta$ is very small, $E_C = k \sec^2 \theta \cdot \Delta\theta$, approximately. The error E_C is extremely large if θ is near 90°, even if $\Delta\theta$ is small; hence this form of galvanometer is not used in accurate work.

EXERCISES

1. At what point on the parabola $y = x^2$ is the tangent parallel to the secant drawn through the points where $x = 0$ and $x = 1$?

2. Proceed as in Ex. 1 for the curve $y = \sin x$, and the points where $x = 60°$ and $x = 75°$.

3. Proceed as in Ex. 1 for the curve $y = \log (1 + x)$, for $x = 1$ and $x = 3$.

4. Discuss the differences in a four-place table of natural sines, the argument interval being $10'$.

5. Proceed as in Ex. 4 for a similar table of natural cosines; of natural tangents.

6. Discuss the differences in a four-place table of logarithmic sines, the entries being given for intervals of $10'$.

7. Proceed as in Ex. 6 for a table of logarithmic tangents.

8. Calculate the difference in a seven-place table of $\log_{10} \sin x$ at the place where $x = 30°$; where $x = 60°$; where $x = 85°$.

9. Discuss the effect of a small change in x on the function $y = \log (1 + 1/x)$.

10. If $\log_{10} N = 1.2070 \pm .0002$, what is the uncertainty in N? [The term $\pm .0002$ indicates the uncertainty in the value 1.2070.]

11. If the angle of elevation of a mountain peak, as measured from a point in the plain 5 mi. distant from it, is $5° \, 20' \pm 5'$, what is the uncertainty in the computed height of the peak?

12. The horizontal range of a gun is $R = (V^2/g) \sin 2\alpha$, where V is the muzzle speed and α the angle of elevation of the gun. If $V = 1200$ ft./sec., discuss the effect upon R of an error of $5'$ in the angle of elevation.

13. The distance to the sea horizon from a point h ft. above sea level is $D = \sqrt{2Rh + h^2}$, where R is the radius of the earth. Discuss the change in D due to a change of one foot in h. (D, R, and h are all to be taken in the same units.) If D is tabulated for values of h at intervals of one foot, what is the tabular difference at the place where $h = 60$?

14. If the boiling point of water at height H ft. above sea level is T, $H = 517\,(212° - T) - (212° - T)^2$, T being the boiling temperature in degrees F. Discuss the uncertainty in H, if T can be measured to $1°$. If H be tabulated with argument T at intervals of $1°$, what is the tabular entry and the tabular difference when $T = 200°$?

15. When a pendulum of length l (feet) swings through a small angle α (radians), the time (seconds) of one swing is $T = \pi\sqrt{l/g}\,(1 + \alpha^2/16)$. What is the effect on T of a change in α, say from $5°$ to $6°$? Of a change in l from 36 in. to 37 in.? Of a change in g from 32.16 to 32.2?

16. The viscosity of water at $\theta°$ C. is $P = 1/(1 + .0337\,\theta + .00022\,\theta^2)$. Discuss the change in P due to a small change in θ. What is the average value of P from $\theta = 20°$ to $\theta = 30°$?

17. The quantity of heat (measured in calories) required to raise one kgm. of water from 0° C. to $\theta°$ C. is $H = 94.21\,(365 - \theta)^{0.3125} + k$. How much heat is required to raise the temperature of one kgm. of water 1° C. when $\theta = 10°$? 20°? 30°? 70°? To find k, observe that $H = 0$ when $\theta = 0$.

18. The coefficient of friction of water flowing through a pipe of diameter D (inches) with a speed V (ft./sec.) is $f = .0126 + (.0315 - .06\,D)/\sqrt{V}$. What is the effect on f of a small change in V? in D?

146. Limit of Error. In using the formula [B] the uncertainty in the value of c is troublesome. If the value of dy/dx at $x = a$ is used in place of its value at $x = c$, the error made in finding Δy by [B] can be expressed in terms of the second derivative d^2y/dx^2.

We shall use the convenient notation $f'(x)$, $f''(x)$, etc., for the derivatives of $f(x)$:

$$f'(x) = \frac{df(x)}{dx} = \frac{dy}{dx} \text{ (the slope of } y = f(x)\text{)}.$$

$$f''(x) = \frac{d^2f(x)}{dx^2} = \frac{d^2y}{dx^2} = \frac{df'(x)}{dx} \text{ (the flexion)}.$$

Let M_2 denote the maximum of the numerical value of $f''(x)$ between two points $x = a$ and $x = b$, so that

(1) $|f''(x)| \leqq M_2$.

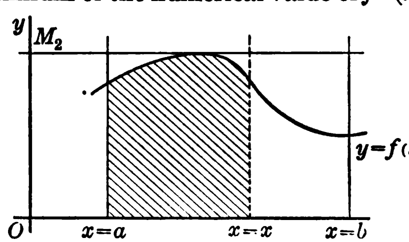

FIG. 76 (*a*).

The area under the curve $y = f''(x)$ between $x = a$ and any point $x = x$ between a and b is evidently not greater than the area under the horizontal line $y = M_2$; that is, if $a < x < b$,

(2) $$\left|\int_{x=a}^{x=x} f''(x)\,dx\right| \leqq \int_{x=a}^{x=x} M_2 dx, \quad \text{or} \quad \left|f'(x)\Big]_{x=a}^{x=x}\right| \leqq M_2 x\Big]_{x=a}^{x=x},$$

since $df'(x)/dx = f''(x)$, and M_2 is a constant; whence, substituting the limits of integration in the usual manner,

(3) $$|f'(x) - f'(a)| \leqq M_2(x - a),$$

which is geometrically shown in Fig. 76 (*b*). It follows that the area under the curve $y = f'(x) - f'(a)$ is not greater than that under the line $y = M_2(x - a)$:

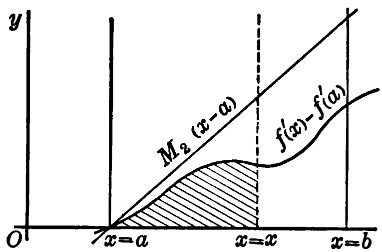

FIG. 76 (*b*).

(4) $$\left|\int_{x=a}^{x=x}[f'(x) - f'(a)]dx\right| \leqq \int_{a=x}^{x=x} M_2(x - a)\,dx;$$

or since $f'(a)$ and M_2 are constants and $df(x)/dx = f'(x)$,

$$\left|\Big[f(x) - f'(a)\cdot x\Big]_{x=a}^{x=x}\right| \leqq M_2 \frac{(x-a)^2}{2}\Bigg]_{x=a}^{x=x};$$

whence, substituting the limits in the usual manner,

[C] $$\left|f(x) - f(a) - f'(a)(x - a)\right| \leqq M_2 \frac{(x-a)^2}{2},$$

which holds for all values of x between $x = a$ and $x = b$. This formula may be written even if $x < a$:

[C*] $$f(x) = f(a) + f'(a)(x - a) + E_2, \text{ where } |E_2| \leqq M_2 \frac{(x-a)^2}{2},$$

and E_2 is the error made in using $f'(a)$ in place of $f'(c)$ in formula [C]; for $(x - a)^2 = |x - a|^2$.

It should be noticed that E_2 is exactly the error made in substituting the tangent at $x = a$ for the curve, *i.e.* it is the difference between $\Delta y[= f(x) - f(a)]$ and $dy[= f'(a)(x - a)]$ mentioned in § 26, p. 43, and shown in Fig. 8.

The formula [B *] is exactly analogous to [C *]; since $\Delta y = f(x) - f(a)$ if $\Delta x = x - a$, [B *] may be written

[B *] $$f(x) = f(a) + E_1, \qquad |E_1| \leqq M_1 \cdot |x - a|.$$

EXAMPLE 1. In Ex. 1, § 145, we found for $L = \log_{10} N$,

$$\Delta L = \frac{.00043}{N} \text{ (nearly).}$$

Applying $[C^*]$, with $f(N) = \log_{10} N$, $a = N$, $x = N + \Delta N$, $x - a = \Delta N = .001$, we find

$$\Delta L = f(N + \Delta N) - f(N) = \frac{.00043}{N} + E_2, \ |E_2| < \frac{.000001}{2} \cdot M_2,$$

where M_2 is the maximum value of $|f''(N)| = (\log_{10} e)/N^2$ between $N = 1$ and $N = 10$. Hence $E_2 < .00000022$ The value of ΔL found before was therefore quite accurate, — absolutely accurate as far as a five-place table is concerned.

EXAMPLE 2. Apply $[C^*]$ to the function $f(x) = \sin x$, with $a = 0$, and show how nearly correct the values are for $x < \pi/90 = 2°$.

Since $f(x) = \sin x$, and $a = 0$, $[C^*]$ becomes

$$\sin x = \sin(0) + \cos(0) \cdot (x - 0) + E_2 = x + E_2, \ |E_2| \leqq M_2 \frac{x^2}{2},$$

where M_2 is the maximum of $|f''(x)| = |-\sin x|$ between 0 and $\pi/90$. that is $M_2 = \sin(\pi/90) = \sin 2° = .0349$ Hence $E_2 < .0175\,x^2$. Since $x < \pi/90$, $x^2 < \pi^2/8100 < .0013$; hence $E_2 < .000023$, and $\sin x = x$ is correct up to $x \leqq \pi/90$ within .000023

Similarly, for $a = \pi/4$, we have, by $[C^*]$,

$$\sin x = \frac{1}{\sqrt{2}}\left[1 + \left(x - \frac{\pi}{4}\right)\right] + E_2, \ |E_2| \leqq M_2 \frac{(x - \pi/4)^2}{2},$$

where $M_2 < 1$. If $(x - \pi/4) < \pi/90$, $|E_2| < (\pi/90)^2 \div 2 = .0007$

147. Extended Law of the Mean. Taylor's Theorem. The formula $[C^*]$ can be extended very readily. Let $f'(x), f''(x), f'''(x), \cdots f^{(n)}(x)$ denote the first n successive derivatives of $f(x)$:

$$f^{(k)}(x) = \frac{d^k f(x)}{dx^k} = \frac{df^{(k-1)}(x)}{dx};$$

and let the maximum of the numerical value of $f^{(n)}(x)$ from $x = a$ to $x = b$ be denoted by M_n. Then

$$|f^{(n)}(x)| \leq M_n,$$

and

$$\left|\int_{x=a}^{x=x} f^{(n)}(x)\,dx\right| \leqq \left|\int_{x=a}^{x=x} M_n\,dx\right|,$$

or $$|f^{(n-1)}(x) - f^{(n-1)}(a)| \leqq |M_n(x-a)|$$

for all values of x between a and b. Integrating again, we obtain, as in § 146:

$$|f^{(n-2)}(x) - f^{(n-2)}(a) - f^{(n-1)}(a)(x-a)| \leqq \left|M_n \frac{(x-a)^2}{2}\right|;$$

and, continuing this process by integrations until we reach $f(x)$, we find:

$$[D] \quad \left|f(x) - f(a) - f'(a)(x-a) - \frac{f''(a)}{2!}(x-a)^2 - \cdots - \frac{f^{(n-1)}(a)}{(n-1)!}(x-a)^{n-1}\right| \leqq M_n \frac{|x-a|^n}{n!}$$

or,

$$[D^*] \quad f(x) = f(a) + f'(a)(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \cdots + \frac{f^{(n-1)}(a)}{(n-1)!}(x-a)^{n-1} + E_n,$$

where

$$|E_n| \leqq M_n \frac{|x-a|^n}{n!},$$

and where M_n is the maximum of $|f^{(n)}(x)|$ between $x = a$ and $x = b$.

This formula is known as the ***extended law of the mean***, or ***Taylor's Theorem***, after Taylor, who first gave such approximations as it expresses. It is one of the more important formulas of the Calculus.

In particular, if $a = 0$, the formula becomes

$$[D^*] \quad f(x) = f(0) + f'(0)x + \frac{f''(0)}{2!}x^2 + \cdots + \frac{f^{(n-1)}(0)}{(n-1)!}x^{n-1} + E_n,$$

where $|E_n| \leqq M_n |x^n| / n!$ This special case of Taylor's Theorem is often called ***Maclaurin's Theorem***.

The formula $[D^*]$ replaces $f(x)$ by a *polynomial* of the nth degree, with an error E_n. These polynomials are represented graphically by curves, which are usually close to the curve which represents $f(x)$ near $x = a$. See *Tables*, III, K.

Since the expression for E_n above contains $n!$ in the denominator, and since $n!$ grows astoundingly large as n grows larger, there is every prospect that E_n will become smaller for larger n; hence, usually, the polynomial curves come closer and closer to $f(x)$ as n increases, and the approximations are reasonably good farther and farther away from $x = a$. But it is never safe to trust to chance in this matter, and it is usually possible to see what *does* happen to E_n as n grows, without excessive work.

EXAMPLE 1. Find an approximating polynomial of the third degree to replace $\sin x$ near $x = 0$, and determine the error in using it up to $x = \pi/18 = 10°$.

Since $f(x) = \sin x$ and $a = 0$, we have $f'(x) = \cos x$, $f''(x) = -\sin x$, $f'''(x) = -\cos x$, $f^{iv}(x) = +\sin x$, whence $f(0) = 0$, $f'(0) = 1$, $f''(0) = 0$, $f'''(0) = -1$; and $[\text{Max.}\,|f^{iv}(x)|] = [\text{Max.}\,|\sin x|] = \sin 10° = .1736$ between $x = 0$ and $x = \pi/18 = 10°$. Hence

$$\sin x = 0 + 1 \cdot (x - 0) + 0 + (-1) \cdot \frac{(x-0)^3}{2 \cdot 3} + E_4 = x - \frac{x^3}{3!} + E_4,$$

where $|E_4| < (.1736) \cdot x^4/4! \leq (.1736)\,(\pi/18)^4 \div 4! < .000007$, when x lies between 0 and $\pi/18$.

In general, the approximation grows better as n grows larger, for $|f^{(n)}(x)|$ is always either $|\sin x|$ or $|\cos x|$; hence $M_n \leq 1$, and $|E_n| \leq x^n/n!$ which diminishes very rapidly as n increases, especially if $x < 1 = 57°.3$ For $n = 7$, the formula gives, for $x > 0$,

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} + E_7, \quad |E_7| < x^7/7!.$$

EXAMPLE 2. Express $\sqrt{1+x}$ as a quadratic in x and estimate the error if x lies between 0 and .2

Here $\quad f(0) = 1; f'(0) = 1/2; f''(0) = -1/4; M_3 \geq |f'''(\theta)| = 3/8.$

Hence $\sqrt{1+x} = 1 + x/2 - x^2/8 + E_3$; $|E_3| < [(3/8)/(3!)]\,(.2)^3 = .0005$

Thus: $\quad \sqrt{1.2} = 1 + .1 - .005 + E_3 = 1.0950 + E_3$; $|E_3| < .0005$

EXERCISES

1. Apply the formula (C^*) to obtain an approximating polynomial of the first degree for $\tan x$, with $a = 0$. Show that the error, when $|x| < \pi/90$, is less than .00003. Draw a figure to show the comparison between $\tan x$ and the approximating linear function.

2. Apply $[D^*]$ to obtain an approximating quadratic for $\cos x$, with $a = 0$. Show that the error, when $|x| < \pi/10$ is less than $(\pi/10)^3 \div 3!$ Draw a figure.

3. Apply $[D^*]'$ to obtain an approximating cubic for $\cos x$, near $x = 0$. Hence show that the formula found in Ex. 2 is really correct, when $|x| < \pi/10$, to within $(\pi/10)^4 \div 4!$ Draw a figure.

4. Obtain an approximation of the third degree for $\sin x$ near $x = \pi/3$. Show that it is correct to within $(\pi/10)^4 \div 4!$ for angles which differ from $\pi/3$ by less than $\pi/10$. Draw a figure.

Obtain an approximation of the first degree, one of the second degree, one of the third degree, for each of the following functions near the value of x mentioned; find an upper limit of the error in each case for values of x which differ from the value of a by the amount specified; draw a figure showing the three approximations in each case:

5. e^x, $a = 0$, $|x - a| < .1$

6. $\tan x$, $a = 0$, $|x - a| < \pi/90$.

7. $\log(1+x)$, $a=0$, $|x-a| < .2$

8. $\cos x$, $a = \pi/4$, $|x-a| < \pi/18$.

9. e^{-x}, $a = 2$, $|x - a| < .5$

10. $\sin x$, $a = \pi/2$, $|x-a| < \pi/45$.

11. $\tan x$, $a = \pi/4$, $|x-a| < \pi/90$.

12. x^2+x+1, $a=1$, $|x-a| < 1/5$.

13. $2x^2 - x - 1$, $a = 1/2$, $|x - a| < 1$.

14. $x^3 - 2x^2 - x + 1$, $a = -2$, $|x - a| < .5$

15. Find a polynomial which represents $\sin x$ to seven decimal places (inclusive), for $|x| < 10°$.

16. Proceed as in Ex. 15, for $\cos x$; for e^{-x}, when $0 < x < 1$.

17. Show that x differs from $\sin x$ by less than .0001 for values of x less than a certain amount; and estimate this amount as well as possible.

18. The quantity of current C (in watts) consumed per candle power by a certain electric lamp in terms of voltage v is $C = 2.7 + 10^{8.007-.0767v}$. Express C by a polynomial in $v - 115$ correct from $v = 110$ up to $v = 120$ to within .025 watt.

148. Application of Taylor's Theorem to Extremes. If a function $y = f(x)$ is given whose maxima and minima are to be found, we may find the critical points where $f'(x) = 0$. Let a be one solution of $f'(x) = 0$, that is, a critical value. Then, since $f'(a) = 0$, we have, by [D^*],

$$\Delta y = f(x) - f(a) = 0 + \frac{f''(a)}{2!}(x-a)^2 + E_3, \; |E_3| \leqq M_3 \frac{(x-a)^3}{3!},$$

where $M_3 \geqq |f'''(x)|$. Hence the sign of Δy is determined by the sign of $f''(a)$ when $(x - a)$ is sufficiently small.

If $f''(a) > 0$, $\Delta y > 0$, and $f(x)$ is a *minimum* at $x = a$.

If $f''(a) < 0$, $\Delta y < 0$, and $f(x)$ is a *maximum* at $x = a$. (See § 42, p. 66.)

If $f''(a) = 0$, the question is not decided.* But in that case, by [D^*]:

$$\Delta y = f(x) - f(a) = 0 + 0 + \frac{f'''(a)}{3!}(x-a)^3 + \frac{f^{\text{iv}}(a)}{4!}(x-a)^4 + E_5,$$

where $|E_5| \leqq M_5 |x-a|^5/5!$, $M_5 \geqq |f^{\text{v}}(x)|$. From this we see that if $f'''(a) \neq 0$ there is *neither* a maximum nor a minimum, for $(x - a)^3$ changes sign near $x = a$. But if $f'''(a) = 0$, then $f^{\text{iv}}(a)$ determines the sign of Δy, as in the case of $f''(a)$ above.

In general, if $f^{(k)}(a)$ is the first one of the successive derivatives, $f'(a), f''(a), \cdots$, which is not zero at $x = a$, then there is:

no extreme if k is odd;

a maximum if k is even and $f^{(k)}(a) < 0$;

a minimum if k is even and $f^{(k)}(a) > 0$.

* The methods which follow are logically sound and can always be carried out when the derivatives can be found. But if several derivatives vanish (or, what is worse, fail to exist), the method of § 34, p. 54, is better in practice.

EXAMPLE 1. Find the extremes for $y = x^4$.

Since $f(x) = x^4$, $f'(x) = 4x^3$; hence the critical values are solutions of the equation $4x^3 = 0$, and therefore $x = 0$ is the only such critical value.

Since $f''(x) = 12x^2$, $f'''(x) = 24x$, $f^{\text{iv}}(x) = 24$, the first derivative which does not vanish at $x = 0$ is $f^{\text{iv}}(x)$, and it is positive $(= 24)$. It follows that $f(x)$ is a *minimum* when $x = 0$; this is borne out by the familiar graph of the given curve.

EXERCISES

Study the extremes in the following functions:

1. x^6.
2. $(x - 2)^3$.
3. $4x^3 - 3x^4$.
4. $x^3(1 + x)^3$.
5. $(x + 3)^5$.
6. $x^4(2x - 1)^3$.
7. $\sin x^3$.
8. $x - \sin x$.
9. $x^2 \sin x$.
10. $x^4 \cos x$.
11. $x^3 \tan x$.
12. e^{-1/x^2}.

13. Discuss the extremes of the curves $y = x^n$, for all positive integral values of n.

14. An open tank is to be constructed with square base and vertical sides so as to contain 10 cu. ft. of water. Find the dimensions so that the least possible quantity of material will be needed.

15. Show that the greatest rectangle that can be inscribed in a given circle is a square.

[See Ex. 44, p. 59. Other exercises from § 35 may be resolved by the process of § 148.]

16. What is the maximum contents of a cone that can be folded from a filter paper of 8 in. diameter?

17. A gutter whose cross section is an arc of a circle is to be made by bending into shape a strip of copper. If the width of the strip is a, show that the radius of the cross section when the carrying capacity is a maximum is a/π. [OSGOOD.]

18. A battery of internal resistance r and E. M. F. e sends a current through an external resistance R. The power given to the external circuit is

$$W = \frac{Re^2}{(R + r)^2}.$$

If $e = 3.3$ and $r = 1.5$, with what value of R will the greatest power be given to the external circuit? [SAXELBY.]

149. Indeterminate Forms. The quotient of two functions is not defined at a point where the divisor is zero. Such quotients $f(x) \div \phi(x)$ at $x = a$, where $f(a) = \phi(a) = 0$, are called ***indeterminate forms***.* We may note that the graph of

$$(1) \qquad q = \frac{f(x)}{\phi(x)}, \qquad (f(a) = \phi(a) = 0),$$

may be quite regular near $x = a$; hence it is natural to make the definition:

$$(2) \qquad q\Big]_{x=a} = \frac{f(x)}{\phi(x)}\Big]_{x=a} = \lim_{x \to a} \frac{f(x)}{\phi(x)}.$$

If we apply [D *], we obtain,

$$q = \frac{f(x)}{\phi(x)} = \frac{0 + f'(a)(x-a) + E_2'}{0 + \phi'(a)(x-a) + E_2''},$$

where

$$|E_2'| \leqq M_2'(x-a)^2/2!, \; |E_2''| \leqq M_2''(x-a)^2/2!,$$

and

$$M_2' \geqq |f''(x)|, \; M_2'' \geqq |\phi''(x)|, \text{ near } x = a.$$

Hence

$$q = \frac{f(x)}{\phi(x)} = \frac{f'(a) + p' M_2' \dfrac{(x-a)}{2}}{\phi'(a) + p'' M_2'' \dfrac{(x-a)}{2}},$$

where p' and p'' are numbers between -1 and $+1$. It follows that

$$(3) \qquad \lim_{x \to a} q = \lim_{x \to a} \frac{f(x)}{\phi(x)} = \frac{f'(a)}{\phi'(a)}$$

unless $\phi'(a) = 0$. But if $\phi'(a) = 0$, q becomes infinite, and the graph of (1) has a *vertical asymptote* at $x = a$ unless

* If $\phi(a) = 0$ but $f(a) \neq 0$ the quotient q evidently becomes infinite; in that case the graph of (1) shows a vertical asymptote.

$f'(a) = 0$ also. If both $f'(a)$ and $\phi'(a)$ are zero, it follows in precisely the same manner as above, that

$$q = \frac{f(x)}{\phi(x)} = \frac{f^{(k)}(a) + p' M'_{k+1} \dfrac{(x-a)}{(k+1)!}}{\phi^{(k)}(a) + p'' M'_{k+1} \dfrac{(x-a)}{(k+1)!}},$$

where either $f^{(k)}(a)$ or $\phi^{(k)}(a)$ is not zero, but all preceding derivatives of both $f(x)$ and $\phi(x)$ are zero at $x = a$; and where $M'_{k+1} \geqq |f^{(k+1)}(x)|$, $M''_{k+1} \geqq |\phi^{(k+1)}(x)|$ near $x = a$ and where p' and p'' are numbers between -1 and $+1$. It follows that

$$\lim_{x \to a} q = \lim_{x \to a} \frac{f(x)}{\phi(x)} \equiv \frac{f^{(k)}(a)}{\phi^{(k)}(a)},$$

provided all previous derivatives of both $f(x)$ and $\phi(x)$ are zero at $x = a$, and provided $\phi^{(k)}(a) \neq 0$. If $\phi^{(k)}(a) = 0$, $f^{(k)}(a) \neq 0$, then q becomes infinite and the graph of (1) has a *vertical asymptote* at $x = a$.

It should be noted that (3) is only a repetition of Rule [VII], p. 31. For if $u = f(x)$ and $v = \phi(x)$, since $f(a) = \phi(a) = 0$,

$$q = \frac{f(x)}{\phi(x)} = \frac{f(x) - f(a)}{\phi(x) - \phi(a)} = \frac{\Delta u}{\Delta v} = \frac{\Delta u}{\Delta x} \div \frac{\Delta v}{\Delta x},$$

where $\Delta x = x - a$; and therefore

$$\lim_{x \to a} q = \lim_{\Delta x \to 0} \frac{\Delta u}{\Delta x} \div \lim_{\Delta x \to 0} \frac{\Delta v}{\Delta x} = \left[\frac{du}{dx} \div \frac{dv}{dx}\right]_{x=a} = \left[\frac{f'(x)}{\phi'(x)}\right]_{x=a} = \frac{f'(a)}{\phi'(a)},$$

provided $\phi'(a)$ is not zero (see Theorem D, p. 15).

EXAMPLE 1. To find $\lim_{x \to 0} [(\tan x) \div x]$.

Here $f(x) = \tan x$, $\phi(x) = x$; $f(0) = \phi(0) = 0$; hence

$$\lim_{x \to 0} \frac{\tan x}{x} = \frac{f'(0)}{\phi'(0)} = \frac{[\sec^2 x]_{x=0}}{1} = 1.$$

Draw the graph $q = (\tan x) \div x$ and notice that this value $q = 1$ fits exactly where $x = 0$.

This limit can be found directly as follows:

$$\lim_{h \to 0} \frac{\tan h}{h} = \lim_{h \to 0} \frac{\tan(0 + h) - \tan(0)}{(0 + h) - (0)} = \frac{d \tan x}{dx}\bigg]_{x=0} = \sec^2 x \bigg]_{x=0} = 1.$$

EXAMPLE 2. To find $\lim\limits_{x\to 0} (1 - \cos x)/x^2$.

Here $f(x) = 1 - \cos x$, $\phi(x) = x^2$; $f(0) = \phi(0) = 0$; $f'(0) = \sin(0) = 0$ and $\phi'(0) = 0$; $f''(x) = \cos x$, $\phi''(x) = 2$; hence

$$\lim_{x\to 0} \frac{1-\cos x}{x^2} = \frac{\cos x}{2}\Big]_{x=0} = \frac{1}{2}$$

Draw the graph of $q = (1 - \cos x)/x^2$, and note that $(x = 0,\ q = 1/2)$ fits it well.

150. Infinitesimals of Higher Order. When the quotient

$$(1)\qquad q = \frac{f(x)}{x^n}$$

approaches a finite number not zero when x is infinitesimal:

$$(2)\qquad \lim_{x\to 0} q = \lim_{x\to 0} \frac{f(x)}{x^n} = k \neq 0,$$

then $f(x)$ is said ***to be an infinitesimal of order n with respect to x.*** An infinitesimal whose order is greater than 1 is called an ***infinitesimal of higher order.***

The equation (2) may be reduced to the form

$$(3)\qquad \lim_{x\to 0} [f(x) - kx^n] = 0,$$

or

$$(4)\qquad f(x) = (k + E)\,x^n,$$

where $\lim E = 0$. The quantity kx^n is called the ***principal part*** of the infinitesimal $f(x)$. The difference $f(x) - kx^n = Ex^n$ is evidently an infinitesimal whose order is greater than n, for

$$\lim (Ex^n \div x^n) = \lim E = 0.$$

Thus by Example 2, § 149, $1 - \cos x$ is an infinitesimal of the second order with respect to x; its principal part is $x^2/2$. Note that

$$1 - \cos x = x^2/2 + px^3/3!,$$

by [D*], where $-1 \leqq p \leqq +1$; the principal part is the first term of Taylor's Theorem that does not vanish.

In general, if we have $f(0) = f'(0) = f''(0) = \cdots = f^{k-1}(0) = 0$, but $f^{k)}(0) \neq 0$, the formula [D*] gives, for $a = 0$,

$$f(x) = f^{(k)}(0)\cdot x^k/k! + p\,M_{k+1}\,x^{k+1}/(k+1)!$$

where $M_{k+1} \geqq |f^{(k+1)}(x)|$ near $x = 0$, and $-1 \leqq p \leqq +1$. Hence $f(x)$ is an infinitesimal of order k, and its principal part is $f^{(k)}(0)\,x^k/k!$.

EXERCISES

Evaluate the indeterminate forms below, in which the notation $\phi(x)\,|_a$ means to determine the limit of $\phi(x)$ when $x = a$. The vertical bar applies to all that precedes it. Draw the graphs as in Exs. 1, 2, above.

1. $\sin x/x\,|_0$. **2.** $\sin 2x/\sin 3x\,|_0$. **3.** $\tan 3x/x|_0$.

4. $\left.\dfrac{x^5-1}{x^2-1}\right|_1$. **5.** $\left.\dfrac{e^{-x}-1}{x}\right|_0$. **6.** $\left.\dfrac{a^x-1}{x}\right|_0$.

7. $\left.\dfrac{\tan 2x}{\tan 3x}\right|_0$. **8.** $\left.\dfrac{e^x-e^{-x}}{x}\right|_0$. **9.** $\left.\dfrac{a^x-b^x}{x}\right|_0$.

10. $\left.\dfrac{\log(1-x)}{\sin x}\right|_0$ **11.** $\left.\dfrac{1-\cos 2x}{x^2}\right|_0$. **12.** $\left.\dfrac{\log x^2}{\sqrt{x^2-1}}\right|_1$.

13. $\left.\dfrac{x-\sin x}{x-\tan x}\right|_0$. **14.** $\left.\dfrac{1+\cos \pi x}{1-x-\log x}\right|_1$ **15.** $\left.\dfrac{\log(1+x)}{\sqrt{1-x}}\right|_1$

16. $\left.\dfrac{x\cos x-\sin x}{x^3}\right|_0$. **17.** $\left.\dfrac{\sin^{-1}x}{\tan^{-1}x}\right|_0$. **18.** $\left.\dfrac{e^x-e^{\sin x}}{x-\sin x}\right|_0$.

19. $\left.\dfrac{a^{\log x}-x}{\log x}\right|_1$. **20.** $\left.\dfrac{\log(x^3-7)}{x^2-5x+6}\right|_2$ **21.** $\left.\dfrac{\sin^{-1}(x-2)}{\sqrt{x^2+x-6}}\right|_2$

22. $\left.\dfrac{\sin^{-1}\sqrt{a^2-x^2}}{\sqrt{a^2-x^2}}\right|_a$.

Determine the order of each of the quantities below when the variable x is the standard infinitesimal:

23. $x-\sin x$. **30.** $x\cos x-\sin x$.

24. e^x-e^{-x}. **31.** $\sin 2x-2\sin x$.

25. $x^2\sin x^2$. **32.** $\log\cos x$.

26. $\log(1+x)-x$. **33.** $\log(1+e^{-1/x})$.

27. $e^x-e^{\sin x}$. **34.** $\tan^{-1}x-\sin^{-1}x$.

28. a^x-1. **35.** $\log\cos x-\sin^2 x$.

29. $\log[(a+x)/(a-x)]$. **36.** $2x-e^x+e^{-x}$.

37. $\cos^{-1}(1-x)-\sqrt{2x-x^2}$.

151. Other Indeterminate Forms. The numerator and denominator can be replaced by their derivatives not only when the fraction takes the form 0/0, but also when it takes

the form ∞/∞ (see Pierpont, *Functions of a Real Variable*, p. 305).

Since $f(x)/\phi(x) = [1/\phi(x)] \div [1/f(x)]$, any fraction that takes one of the two forms $0/0$, $\infty \div \infty$, can also be put into the other form. Thus, as $x \to \pi/2$, $\tan x$ and $\sec x$ both become infinite, while $\operatorname{ctn} x$ and $\cos x$ approach zero; hence

$$\lim_{x\to\pi/2} \frac{\tan x}{\sec x} = \lim_{x\to\pi/2} \frac{\cos x}{\operatorname{ctn} x} = 1.$$

Likewise, if $f(x) \to 0$ as $\phi(x)$ becomes infinite, their product is of the form $0 \times \infty$, and it can be put into either of the preceding forms.

Thus, as $x \to 0$, $\log x$ becomes $-\infty$; so that

$$\lim_{x\to 0} (x \log x) = \lim_{x\to 0} \frac{\log x}{1/x} = \lim_{x\to 0} \frac{1/x}{-1/x^2} = \lim_{x\to 0} (-x) = 0.$$

Other indeterminate forms are $\infty - \infty$, 1^∞, 0^0, ∞^0. All these can be made to depend on the forms already considered. For let α, β, γ, δ, ϵ, be variables simultaneously approaching, respectively, ∞, ∞, 1, 0, 0. Then $\alpha - \beta$, γ^α, δ^ϵ, α^ϵ take, respectively, the preceding four indeterminate forms. But

$$\lim (\alpha - \beta) = \lim \frac{1/\beta - 1/\alpha}{1/\beta\alpha},$$

which is of the form $0/0$; while the logarithms of the others,

$$\log \gamma^\alpha = \alpha \log \gamma, \quad \log \delta^\epsilon = \epsilon \log \delta, \quad \log \alpha^\epsilon = \epsilon \log \alpha,$$

are each of the form $0 \times \infty$.

Example 1. Thus, when $x \to \pi/2$, $(\sin x)^{\tan x}$ takes the form 1^∞. But

$$(\sin x)^{\tan x} = e^{[\log \sin x]/\operatorname{ctn} x},$$

which approaches the same limit as $e^{-\operatorname{ctn} x/\csc^2 x}$, as $x \to \pi/2$, and this limit is evidently $e^0 = 1$.

Example 2. Similarly, when x becomes infinite, $(1/x)^{1/(2x+1)}$ takes the form 0^0. It may be written in the form,

$$e^{[-\log x]/(2x+1)},$$

which approaches the same limit as $e^{-1/2x}$, that is, the limit is $e^0 = 1$, as $x \to \infty$.

Example 3. As an example of the last form, ∞^0, take $(1/x)^x$ as $x \to 0$. This becomes

$$e^{-x \log x},$$

and approaches $e^0 = 1$, as $x \to 0$.

Indeterminate forms in two variables cannot be evaluated, unless one knows a law connecting the variables as they approach their limits, which practically reduces the problem to a problem in one letter.

EXERCISES

Evaluate each of the following indeterminate forms, where $\phi(x)|_a$ means the limit of $\phi(x)$ as x approaches a. Draw a graph in each case.

1. $\left.\dfrac{x}{e^x}\right|_\infty$.
2. $\left.\dfrac{\log \operatorname{ctn} x}{\log \cos x}\right|_{\pi/2}$.
3. $\left.\dfrac{\sec x}{\log(\pi/2 - x)}\right|_{\pi/2}$.
4. $\left.\dfrac{x^3}{e^x}\right|_\infty$.
5. $\left.\dfrac{\log \cos x}{\sin^2 x}\right|_0$.
6. $\left.\dfrac{\log \sin^2 x}{\log \tan^3 x}\right|_0$.
7. $\left.\dfrac{x^n}{e^x}\right|_\infty$.
8. $\left.\dfrac{\log x}{2^x}\right|_\infty$.
9. $\left.\dfrac{\log z}{\sqrt{z}}\right|_\infty$.
10. $x^2 \operatorname{ctn} x\,|_0$.
11. $x^2 \log x^3\,|_0$.
12. $(\tan x - \sec x)\,|_{\pi/2}$.
13. $x^{\sin x}\,|_0$.
14. $(1 + x)^{1/x}\,|_0$.
15. $(1 + n/x)^x\,|_\infty$.
16. $(\tan x)^{\cos x}\,|_{\pi/2}$.
17. $(\sin ax)^{\sin bx}\,|_0$.
18. $\left.\left(\tan x - \dfrac{1}{\pi/2 - x}\right)\right|_{\pi/2}$.

Find the value of each of the following improper integrals, using Table V, F, when necessary after integrating by parts:

19. $\int_0^\infty x\, e^{-x}\, dx$.
20. $\int_0^\infty x^2\, e^{-x}\, dx$.
21. $\int_0^\infty x^{1.2}\, e^{-x}\, dx$.

152. Infinite Series. An *infinite series* is an indicated sum of an unending sequence of terms:

(1) $$a_0 + a_1 + a_2 + \cdots + a_n + \cdots;$$

this has no meaning whatever until we make a definition, for it is impossible to *add* all these terms. Let us take the sum of the first n terms:

$$s_n = a_0 + a_1 + a_2 + \cdots + a_{n-1},$$

which is perfectly finite; if the limit of s_n exists as n becomes infinite, that limit is called the ***sum of the series*** (1):

(2) $$S = \lim_{n\to\infty} s_n = a_0 + a_1 + \cdots + a_n + \cdots$$

If $\lim\limits_{n\to\infty} s_n = S$ exists, the series is called ***convergent***; if S does not exist, the series is called ***divergent***; if the series

formed by taking the numerical (or absolute) values of the terms of (1) converges, then (1) is called ***absolutely convergent***. Infinite series which converge absolutely are most convenient in actual practice, for extreme precaution is necessary in dealing with other series. (See § 154. See also Goursat-Hedrick, *Mathematical Analysis*, Vol. I, Chap. VIII.)

EXAMPLE 1. The series $1 + r + r^2 + \cdots + r^n + \cdots$ is called a ***geometric series;*** the number r is called the ***common ratio.*** A geometric series *converges absolutely for any value of r numerically less than* 1; for

$$s_n = 1 + r + r^2 + \cdots + r^{n-1} = \frac{1}{1-r} - \frac{r^n}{1-r},$$

hence

$$\lim_{n\to\infty}\left|\frac{1}{1-r} - s_n\right| = \lim_{n\to\infty}\left|\frac{r^n}{1-r}\right| = 0, \text{ if } |r| < 1,$$

since r^n decreases below any number we might name as n becomes infinite. It follows that the ***sum*** S of the infinite series is

$$S = \lim_{n\to\infty} s_n = \frac{1}{1-r}, \text{ if } |r| < 1;$$

and it is easy to see that the series still converges if r is negative, when it is replaced by its numerical value $|r|$.

EXAMPLE 2. Any series $a_0 + a_1 + a_2 + \cdots + a_n + \cdots$ of positive numbers can be compared with the geometric series of Ex. 1. Let

$$\sigma_n = a_0 + a_1 + a_2 + \cdots + a_{n-1};$$

then it is evident that σ_n increases with n. Comparing with the geometric series $a_0\,(1 + r + r^2 + \cdots + r^n + \cdots)$, it is clear that if

$$a_n \leqq a_0 r^n, \quad \sigma_n \leqq a_0 s_n,$$

where $s_n = 1 + r + \cdots + r^{n-1}$. *Hence σ_n approaches a limit if s_n does,* i.e. *if* $0 < r < 1$. It follows that the given series converges if a value of $r < 1$ can be found for which $a_n \leqq a_0 r^n$, that is, for which $a_n \div a_{n-1} \leqq r < 1$. There are, however, some convergent series for which this test cannot be applied satisfactorily. It may be applied in testing any series for absolute convergence; or in testing any series of positive terms. For example, consider the series

$$1 + \frac{1}{1\,!} + \frac{1}{2\,!} + \frac{1}{3\,!} + \cdots + \frac{1}{n\,!} + \cdots;$$

here $a_n = 1/n!$, $a_{n-1} = 1/(n-1)!$, and therefore $a_n/a_{n-1} = (n-1)!/n!$ $= 1/n$. Hence $a_n/a_{n-1} < 1/2$ when $n \geqq 2$,

$$\sigma_n = 1 + \frac{1}{1!} + \frac{1}{2!} + \cdots + \frac{1}{(n-1)!} > 1 + \left(1 + \frac{1}{2} + \frac{1}{2^2} + \cdots + \frac{1}{2^{n-2}}\right)$$
$$= 1 + s_{n-1},$$

where $s_{n-1} = 1 + r + \cdots + r^{n-2}$, $r = 1/2$. It follows that the given series converges and that its sum is less than $1 + 2 = 3$. [Compare § 154, p. 269; it results that $s < 3$. Compare Ex. 2, p. 268.]

153. Taylor Series. General Convergence Test. Series which resemble the geometric series except for the insertion of constant coefficients of the powers of r,

$$(1) \qquad A + Br + Cr^2 + Dr^3 + \cdots,$$

arise through application of Taylor's Theorem [D *], § 147, p. 254; such series are called ***Taylor series*** or ***power series.*** The properties of a Taylor series are, like those of a geometric series, comparatively simple. Comparing (1) with [D *], we see that r takes the place of $(x-a)$, while $A, B, C, D, \cdots$ have the values:

$$A = f(a), B = \frac{f'(a)}{1!}, C = \frac{f''(a)}{2!}, D = \frac{f'''(a)}{3!} \cdots.$$

If we consider the sum of n such terms:

$$s_n = f(a) + \frac{f'(a)}{1!}(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \cdots$$
$$+ \frac{f^{(n-1)}(a)}{(n-1)!}(x-a)^{n-1},$$

we see by [D *], that

$$f(x) = s_n + E_n, \text{ where } |E_n| \leqq M_n \frac{|x-a|^n}{n!}, M_n \geqq |f^{(n)}(x)|;$$

or

$$s_n = f(x) - E_n.$$

It follows that *if E_n approaches zero as n becomes infinite, the infinite Taylor Series*

$$[D^{**}] \quad f(x) = f(a) + \frac{f'(a)}{1!}(x-a) + \frac{f''(a)}{2!}(x-a)^2 + \cdots + \frac{f^n(a)}{n!}(x-a)^n + \cdots$$

*converges, and its sum is $S = \lim s_n = f(x)$.**
This is certainly true, for example, whenever $|f^{(n)}(x)|$ remains, for all values of n, less than some constant C, however large, for all values of x between $x = a$ and $x = b$. For in that case

$$\lim_{n\to\infty} |E_n| \leqq \lim_{n\to\infty} C \cdot \frac{|x-a|^n}{n!} = C \lim_{n\to\infty} \frac{|x-a|^n}{n!} = 0$$

for all values of $(x - a)$.† When $|f^{(n)}(x)|$ grows larger and larger without a bound as n becomes infinite, we may still often make $|E_n|$ approach zero by making $(x - a)$ numerically small.

EXAMPLE 1. Derive an infinite Taylor series in powers of x for the function $f(x) = \sin x$.

Since $f(x) = \sin x$, we have $f'(x) = \cos x$, $f''(x) = -\sin x$, and, in general, $f^{(n)}(x) = \pm \sin x$, or $\pm \cos x$; hence

$$|f^n(x)| \leqq 1, \lim_{n\to\infty} |E_n| \leqq \lim_{n\to\infty} \frac{x^n}{n!} = 0;$$

therefore the infinite series $[D^{**}]$ for $a = 0$ is

$$\sin x = 0 + x + 0 - \frac{1}{3!}x^3 + 0 + \frac{1}{5!}x^5 + \cdots;$$

this series certainly converges and its sum is $\sin x$ for all values of x, since $\lim |E_n| = 0$.

* This result is forecasted in § 147.

† This results from the fact that n eventually exceeds $(x-a)$ numerically; afterwards an increase in n diminishes the value of E_n more and more rapidly as n grows.

EXAMPLE 2. Derive an infinite series for e^x in powers of $(x-2)$.

Since $f(x)=e^x$, we have $f'(x)=e^x, \cdots, f^{(n)}(x)=e^x$; hence $f(2)=e^2$, $f'(2)=e^2, \cdots, f^{(n)}(2)=e^2$, and $|f^{(n)}(x)| \leqq e^b$ where b is the largest value of x we shall consider. Then the series

$$e^x = e^2 + e^2(x-2) + \frac{e^2}{2!}(x-2)^2 + \cdots + \frac{e^2}{n!}(x-2)^n + \cdots$$

$$= e^2\left[1 + (x-2) + \frac{1}{2!}(x-2)^2 + \cdots + \frac{1}{n!}(x-2)^n + \cdots\right]$$

converges and its sum is e^x, for all values of x less than b; for

$$\lim_{n\to\infty} |E_n| \leqq \lim_{n\to\infty} \frac{e^b|x-2|^n}{n!} = 0.$$

Since b is any number we please, the series is convergent and its sum is e^x for all values of x.

EXERCISES

Derive the following series, and show, when possible, that they converge for the indicated values of x.

1. $\cos x = 1 - x^2/2! + x^4/4! - x^6/6! + \cdots$; (all x).
2. $e^x = 1 + x + x^2/2! + x^3/3! + \cdots$; (all x).
3. $e^{-x} = 1 - x + x^2/2! - x^3/3! + \cdots$; (all x).
4. $\tan x = x + x^3/3 + 2x^5/15 + 17x^7/315 + \cdots$; $(|x| < \pi/4)$.
5. $\log(1+x) = x - x^2/2 + x^3/3 - x^4/4 + \cdots$; $(|x| < 1)$.
6. $\sinh x = (e^x - e^{-x})/2 = x + x^3/3! + x^5/5! + \cdots$; (all x).
7. $\cosh x = (e^x + e^{-x})/2 = 1 + x^2/2! + x^4/4! + \cdots$; (all x).
8. $\tanh x = \sinh x/\cosh x = x - x^3/3 + 2x^5/15 - 17x^7/315 + \cdots$; (all x).

9. Show that the series of Ex. 6 can be obtained from those of Exs. 2 and 3 if the terms are combined separately.

10. Show that the series of Ex. 3 results from the series of Ex. 2 if x is replaced by $-x$.

11. Obtain the series for $\sin x$ in powers of $(x - \pi/4)$.

12. Obtain the series for e^x in terms of powers of $(x-1)$.

13. Obtain the series for $\log x$ in powers of $(x-1)$. Compare it with the series of Ex. 5.

14. Obtain the series for $\log(1-x)$ in powers of x, directly; also by replacing x by $-x$ in Ex. 5.

15. Using the fact that $\log[(1+x)/(1-x)] = \log(1+x) - \log(1-x)$, obtain the series for $\log[(1+x)/(1-x)]$ by combining the separate terms of the two series of Ex. 14 and of Ex. 5. This series is actually used for computing logarithms.

16. Show that the terms of the Maclaurin series for $(a+x)^n$ in powers of x are precisely those of the usual binomial theorem.

17. Show that the series for e^{a+x} in powers of x is the same as the series for e^x all multiplied by e^a.

18. Show that the series for 10^x is the same as the series for e^x with x replaced by x/M, where $M = 2.30\cdots$.

154. Precautions about Infinite Series. There are several popular misconceptions concerning infinite series which yield to very commonplace arguments.

(*a*) *Infinite series are never used in computation.* Contrary to a popular belief infinite series are never used in computation. What is actually done is to use a few terms (that is, a polynomial) for actual computation; one may or may not consider how much error is made in doing this, with an obvious effect on the trustworthiness of the result.

Thus we may write

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \cdots \pm \frac{x^{2k+1}}{(2k+1)!} \mp \cdots \text{ (forever)};$$

but in practical computation, we decide to use a few terms, say $\sin x = x - x^3/3! + x^5/5!$. The error in doing this can be estimated by § 147, p. 253. It is $|E_7| \leqq |x^7/7!|$. For reasonably small values of x [say $|x| < 14° < 1/4$ (radians)], $|E_7|$ is exceedingly small.

Many of the more useful series are so rapid in their convergence that it is really quite safe to use them without estimating the error made; but if one proceeds without any idea of how much the error amounts to, one usually computes more terms than necessary. Thus if it were required to calculate sin 14° to eight decimal places, most persons would suppose it necessary to use quite a few terms of the preceding series, if they had not estimated E_7.

(*b*) *No faith can be placed in the fact that the terms are becoming smaller.* The instinctive feeling that if the terms become quite small, one can reasonably stop and suppose the error small, is unfortunately not justified.*

Thus the series

$$\frac{1}{10}+\frac{1}{20}+\frac{1}{30}+\frac{1}{40}+\cdots+\frac{1}{10\,n}+\cdots$$

has terms which become small rather rapidly; one instinctively feels that if about one hundred terms were computed, the rest would not affect the result very much, because the next term is .001 and the succeeding ones are still smaller. *This expectation is violently wrong.*

As a matter of fact this series *diverges;* we can pass any conceivable amount by continuing the term-adding process. For

$$\begin{aligned} \tfrac{1}{30}+\tfrac{1}{40} &> 2\cdot\tfrac{1}{40} \;\;= \tfrac{1}{20},\\ \tfrac{1}{50}+\tfrac{1}{60}+\cdots+\tfrac{1}{80} &> 4\cdot\tfrac{1}{80} \;\;= \tfrac{1}{20},\\ \tfrac{1}{90}+\tfrac{1}{100}+\cdots+\tfrac{1}{160} &> 8\cdot\tfrac{1}{160} = \tfrac{1}{20}, \end{aligned}$$

and so on; groups of terms which total more than 1/20 continue to appear forever; twenty such groups would total over 1; 200 such groups would total over 10; and so on. The preceding series is therefore very deceptive; practically it is useless for computation, though it might appear quite promising to one who still trusted the instinctive feeling mentioned above.

(*c*) *If the terms are alternately positive and negative, and if the terms are numerically decreasing with zero as their limit, the instinctive feeling just mentioned in* (*b*) ***is actually correct:*** the series $a_0 - a_1 + a_2 - a_3 + \cdots$ converges if a_n approaches zero; the error made in stopping with a_n is less than a_{n+1}.†

For, the sum $s_n = a_0 - a_1 + \cdots \pm a_{n-1}$ evidently alternates between an increase and a decrease as n increases, and this

* This fallacious instinctive feeling is doubtless actually *used*, and it is responsible for more errors than any other single fallacy. The example here mentioned is certainly neither an unusual nor an artificial example.

† One must, however, make quite sure that the terms actually approach *zero*, not merely that they become rather small; the addition of .0000001 to each term would often have no appreciable effect on the appearance of the first few terms, but it would make any convergent series diverge.

alternate swinging forward and then backward dies out as n increases, since a_n is precisely the amount of the nth swing.

On each swing s_n passes a point S which it again repasses on the return swing; and its distance from that point is never more than the next swing, — never more than a_{n+1}. Since a_n approaches zero, s_n approaches S, as n becomes infinite.

Thus the series for $\sin x$ is particularly easy to use in calculation: the error made in using $x - x^3/3!$ in place of $\sin x$ is certainly less than $x^5/5!$. The test of § 147 shows, in fact, that the error $|E_5| < M_5 |x^5/5!|$, where $M_5 = 1$.

The similar series for e^x:

$$e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \cdots + \frac{x^n}{n!} + \cdots$$

is not quite so convenient, since the swings are all in one direction for positive values of x; certainly the error in stopping with any term is greater than the first term omitted. The error can be estimated by § 147, p. 253; thus E_5 (for $x > 0$) is less than $M_5 x^5/5!$, where M_5 is the maximum of $f^{\text{v}}(x) = e^x$ between $x = 0$ and $x = x$, *i.e.* e^x; hence $E_5 < e^x x^5/5!$. Note that $e^x > 1$ for $x > 0$.

Another means of convincing oneself that the preceding series converges for $x \leqq 1$ is by comparison with a geometric series with a ratio $x/2$, as in Example 2, p. 265. But this method would require the computation of a vast number of terms, to make sure that the error is small.

(*d*) *A consistently small error in the values of a function may make an enormous error in the values of its derivative.*

Thus the function $y = x - .00001 \sin (100000\,x)$ is very well approximated by the single term $y = x$, — in fact the graphs drawn accurately on any ordinary scale will not show the slightest trace of difference between the two curves. Yet the slope of $y = x$ is always 1, while the slope of $y = x - .00001 \sin (100000\ x)$ oscillates between 0 and 2 with extreme rapidity. Draw the curves, and find dy/dx for the given function.

One advantage in Taylor series and Taylor approximating polynomials is the known fact — proved in advanced texts —

that *differentiation as well as integration is quite reliable on any valid Taylor approximation.**

Thus an attempt to expand the function $y = x - .00001 \sin(100000x)$ in *Taylor* form gives

$$y = x - \left[x - \frac{100000^2}{3!}x^3 + \frac{100000^4}{5!}x^5 - \cdots\right],$$

which would never be mistaken for $y = x$ by any one; the series indeed converges and represents y for every value of x, but a very hasty examination is sufficient to show that an enormous number of terms would have to be taken to get a reasonable approximation, and no one would try to get the derivative by differentiating a single term.

If the relation expressed by the given equation was obtained by experiment, however, no reliance can be placed in a formal differentiation, even though Taylor approximations are used, for minute experimental errors may cause large errors in the derivative. Attention is called to the fact that the preceding example is not an unnatural one, — precisely such rapid minute variations as it contains occur very frequently in nature.

EXERCISES

1. Show that the series obtained by long division for $1 \div (1 + x)$ is the same as that given by Taylor's Series.

2. Obtain the series for $\log(1 + x)$ (see Ex. 5, § 153), by integrating the terms of the series found in Ex. 1 separately.

3. Find the first four terms of the series for $\sin^{-1} x$ in powers of x directly; then also by integration of the separate terms of the series for $1/\sqrt{1 - x^2}$.

4. Proceed as in Ex. 3 for the functions $\tan^{-1} x$ and $1/(1 + x^2)$.

5. Show that the series for $\cos x$ in powers of x is obtained by differentiating separately the terms of the series for $\sin x$.

6. Show that repeated differentiation or integration of the separate terms of the series for e^x always results in the same series as the original one.

7. From the series for $\tan^{-1} x$ compute π by using the identity $\pi/4 = 4 \tan^{-1}(1/5) - \tan^{-1}(1/239)$.

* See, *e.g.*, Goursat-Hedrick, *Mathematical Analysis*, Vol. I, p. 380.

8. The Gudermannian of x is $gd(x) = 2 \tan^{-1} e^x - \pi/2$; expand in powers of x, calculate $gd(.1) = 5° 43'$, and $gd(.7) = 37° 11'$.

9. The "error integral" is $P(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-x^2}\, dx$. Express $P(x)$ as a series in powers of x; calculate $P(.1) = .1125$, $P(1) = .8427$, $P(2) = .9953+$.

10. Show that $\int_0^1 \frac{\cos x}{\sqrt{x}}\, dx = 1.81^-$.

11. Show that $\int_0^3 \frac{\sin x}{\sqrt{x}}\, dx = 1.78^+$.

12. Show that $\int_0^{\pi/2} \sin^{5/4} x\, dx = .9309+$.

13. Show that $\int_0^{1/2} dt/\sqrt{1-t^3} = .508+$.

14. Show that $\int_0^1 dt/\sqrt{1-t^4} = 1.311+$.

CHAPTER XVII

PARTIAL DERIVATIVES — APPLICATIONS

155. Partial Derivatives. If one quantity depends upon two or more other quantities, its rate of change with respect to one of them, while all the rest remain fixed, is called a ***partial derivative.****

If $z = f(x, y)$ is a function of x and y, then, for a constant value of y, $y = k$, z is a function of x alone: $z = f(x, k)$; the derivative of this function of x alone is called the ***partial derivative*** of ***z with respect to x***, and is denoted by any one of the symbols

$$\frac{\partial z}{\partial x} = \frac{\partial f(x, y)}{\partial x} = f_x(x, y) = \frac{df(x, k)}{dx}$$
$$= \lim_{\Delta x \to 0} \frac{f(x + \Delta x, k) - f(x, k)}{\Delta x}.$$

A precisely similar formula defines the partial derivative of z with respect to y which is denoted by $\partial z/\partial y$.

In general, if u is a function of any number of variables x, y, z, $\cdots$, and if one calculates the first derivative of u with respect to each of these variables, supposing all the others to be fixed, the results are called the first partial derivatives of u with respect to $x, y, z, \cdots$, respectively, and are denoted by the symbols

$$\partial u/\partial x, \ \partial u/\partial y, \ \partial u/\partial z, \cdots.$$

* This notion is perhaps more prevalent in the world at large than the notion of a derivative of a function of one variable, because quantities in nature usually depend upon a great many influences. The notion of *partial derivative* is what is expressed in the ordinary phrases "the rate at which a quantity changes, everything else being supposed equal," or ". . . other things being the same."

EXAMPLE 1. Given $z = x^2 + y^2$, to find $\partial z/\partial x$ and $\partial z/\partial y$.

To find $\partial z/\partial x$, think of y as constant: $y = k$; then

$$\frac{\partial z}{\partial x} = \frac{\partial (x^2 + y^2)}{\partial x} = \frac{d\,(x^2 + k^2)}{dx} = 2\,x; \ \frac{\partial z}{\partial y} = 2\,y.$$

EXAMPLE 2. Given $z = x^2 \sin(x + y^2)$, to find $\partial z/\partial x$ and $\partial z/\partial y$.

$$\frac{\partial z}{\partial x} = \frac{\partial\,\{x^2 \sin\,(x + y^2)\}}{\partial x} = \left[\frac{d\,\{x^2 \sin\,(x + k^2)\}}{dx}\right]_{y=k}$$

$$= 2\,x \sin\,(x + y^2) + x^2 \cos\,(x + y^2).$$

$$\frac{\partial z}{\partial y} = \frac{\partial\,\{x^2 \sin\,(x + y^2)\}}{\partial y} = \left[\frac{d\,\{k^2 \sin\,(k + y^2)\}}{dy}\right]_{x=k}$$

$$= 2\,x^2\,y \cos\,(x + y^2).$$

156. Higher Partial Derivatives. Successive differentiation is carried out as in the case of ordinary differentiation. There are evidently four ways of getting a ***second*** partial derivative: differentiating twice with respect to x; once with respect to x, and then once with respect to y; once with respect to y, and then once with respect to x; twice with respect to y. These four second derivatives are denoted, respectively, by the symbols

$$\frac{\partial}{\partial x}\left(\frac{\partial z}{\partial x}\right) = \frac{\partial^2 z}{\partial x^2} = f_{xx}(x, y); \ \frac{\partial}{\partial y}\left(\frac{\partial z}{\partial x}\right) = \frac{\partial^2 z}{\partial y\,\partial x} = f_{xy}(x, y);$$

$$\frac{\partial}{\partial y}\left(\frac{\partial z}{\partial y}\right) = \frac{\partial^2 z}{\partial y^2} = f_{yy}(x, y); \ \frac{\partial}{\partial x}\left(\frac{\partial z}{\partial y}\right) = \frac{\partial^2 z}{\partial x\,\partial y} = f_{yx}(x, y).$$

There is no new difficulty in carrying out these operations; in fact the situation is simpler than one might suppose, for it turns out that the two cross derivatives f_{xy} and f_{yx} are always equal; the order of differentiation is immaterial.*

A similar notation is used for still higher derivatives:

$$f_{xxx} = \frac{\partial^3 z}{\partial x^3} = \frac{\partial}{\partial x}\left(\frac{\partial^2 z}{\partial x^2}\right); \ f_{yxx} = \frac{\partial^3 z}{\partial y\,\partial x^2} = \frac{\partial}{\partial y}\left(\frac{\partial^2 z}{\partial x^2}\right);$$

etc., and the order of differentiation is immaterial.

*At least if the derivatives are themselves continuous. See Goursat-Hedrick, *Mathematical Analysis*, Vol. I, p. 13.

The ***order*** of a partial derivative is the total number of successive differentiations performed to obtain it. The partial derivatives of the first and second orders are very frequently represented by the letters p, q, r, s, t:

$$p = \frac{\partial z}{\partial x}, q = \frac{\partial z}{\partial y}, r = \frac{\partial^2 z}{\partial x^2}, s = \frac{\partial^2 z}{\partial x\, \partial y} = \frac{\partial^2 z}{\partial y\, \partial x}, t = \frac{\partial^2 z}{\partial y^2}.$$

EXAMPLE 1. Given $z = x^2 \sin(x + y^2)$, show that $f_{xy} = f_{yx}$.

Continuing Example 2, § 155, we find:

$$\frac{\partial^2 z}{\partial y\, \partial x} = \frac{\partial}{\partial y}\left(\frac{\partial z}{\partial x}\right) = \frac{\partial}{\partial y}\left[2x \sin(x + y^2) + x^2 \cos(x + y^2)\right]$$
$$= 4xy \cos(x + y^2) - 2x^2 y \sin(x + y^2).$$

$$\frac{\partial^2 z}{\partial x\, \partial y} = \frac{\partial}{\partial x}\left(\frac{\partial z}{\partial y}\right) = \frac{\partial}{\partial x}\left[2x^2 y \cos(x + y^2)\right]$$
$$= 4xy \cos(x + y^2) - 2x^2 y \sin(x + y^2).$$

EXERCISES

Find the first and second partial derivatives, $\partial z/\partial x$, $\partial z/\partial y$, $\partial^2 z/\partial x^2$, $\partial^2 z/\partial x\, \partial y$, $\partial^2 z/\partial y\, \partial x$, and $\partial^2 z/\partial y^2$ for each of the following functions. In each case verify the fact that $\partial^2 z/\partial x\, \partial y = \partial^2 z/\partial y\, \partial x$.

1. $z = x^2 - y^2$.
2. $z = x^2 y + xy^2$.
3. $z = \sin(x^2 + y^2)$.
4. $z = e^{ax+by}$.
5. $z = \tan^{-1}(y/x)$.
6. $z = e^x \sin y$.
7. $z = (x + y)\, e^{x^2+y^2}$.
8. $z = (xy - 2y^2)^{5/3}$.
9. $z = \log(x^2 + y^2)^{1/2}$.

10. The volume of a right circular cylinder is $v = \pi r^2 h$. Find the rate of change of the volume with respect to r when h is constant, and express it as a partial derivative. Find $\partial v/\partial h$, and express its meaning.

11. The pressure p, the volume v, and temperature θ of a gas are connected by the relation $pv = k\theta$, where θ is measured from the absolute zero, $-273°$ C. Assuming θ constant, find $\partial p/\partial v$ and express its meaning. If the volume is constant, express the rate of change of pressure with respect to the temperature as a derivative, and find its value.

12. Find the rate of change of the volume of a cone with respect to its height, if the radius is constant; and the rate of change of the volume with respect to the radius, if the height is a constant.

13. Show that the functions in Exercises 1, 5, 6, and 9 satisfy the equation $\partial^2 z/\partial x^2 + \partial^2 z/\partial y^2 = 0$.

14. A point moves parallel to the x-axis. What are the rates of change of its polar coordinates with respect to x?

15. Show that the rate of change of the total surface of a right circular cylinder with respect to its altitude is $\partial A/\partial h = 2\pi r$; and that its rate of change with respect to its radius is $\partial A/\partial r = 2\pi h + 4\pi r$.

16. Calculate the rate of change of the hypotenuse of a right triangle relative to a side, the other side being fixed; relative to an angle, the opposite side being fixed.

17. Two sides and the included angle of a parallelogram are a, b, C, respectively. Find the rate of change of the area with respect to each of them, the other two being fixed; the same for the diagonal opposite to C.

18. In a steady electric current $C = V \div R$, where C, V, R, denote the current, the voltage (electric pressure), and the resistance, respectively. Find $\partial C/\partial V$ and $\partial C/\partial R$, and express the meaning of each of them.

157. Geometric Interpretation. The first partial derivatives of a function of two independent variables

$$z = f(x, y)$$

can be interpreted geometrically in a simple manner. This equation represents a surface, which may be plotted by erecting at each point of the xy-plane a perpendicular of length $f(x, y)$; the upper ends* of these perpendiculars are the points of the surface.

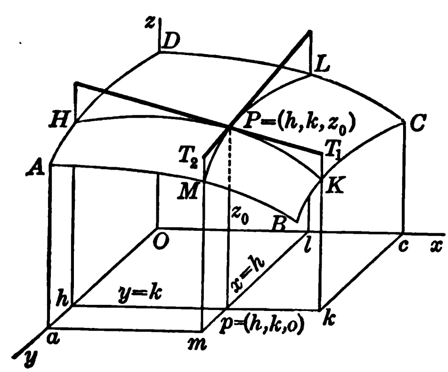

FIG. 77.

Let $ABCD$ be a portion of this sur-

* If z is negative, of course the lower end is the one to take.

face lying above an area *abcd* of the xy-plane. If x varies while y remains fixed, say equal to k, there is traced on the surface the curve HK, the section of the surface by the plane $y = k$. The slope of this curve is $\partial z/\partial x$.

Similarly, $\partial z/\partial y$ is the slope of the curve cut from the surface by a plane $x = h$.

158. Total Derivative. If in addition to the function $z = f(x, y)$, *a relation between x and y, say $y = \phi(x)$, is given, z reduces by simple substitution to a function of one variable*:

$$z = f(x, y),\ y = \phi(x) \text{ gives } z = f(x, \phi(x)).$$

Now any change Δx in x forces a change Δy in y; hence y *cannot* remain constant (unless, indeed, $\phi(x) = \text{const.}$). Hence the change Δz in the value of z is due both to the direct change Δx in x and also to the *forced* change Δy in y. We shall call

$$\Delta z = \text{the total change in } z = f(x + \Delta x, y + \Delta y) - f(x, y),$$

$$\Delta_x z = \text{the partial change due to } \Delta x \text{ directly}$$
$$= f(x + \Delta x, y) - f(x, y),$$

$$\Delta_y z = \text{the partial change } \textit{forced} \text{ by the } \textit{forced} \text{ change } \Delta y$$
$$= \Delta z - \Delta_x z, = f(x + \Delta x, y + \Delta y) - f(x + \Delta x, y).$$

It follows that

$$(1)\quad \frac{dz}{dx} = \lim_{\Delta x \to 0} \frac{\Delta z}{\Delta x} \qquad \left\{ = \lim_{\Delta x \to 0} \left(\frac{f(x+\Delta x, y+\Delta y) - f(x, y)}{\Delta x} \right) \right\};$$

$$= \lim_{\Delta x \to 0} \frac{\Delta_x z + \Delta_y z}{\Delta x} \quad \left\{ = \lim_{\substack{\Delta x \to 0 \\ \Delta y \to 0}} \left(\frac{f(x+\Delta x, y) - f(x, y)}{\Delta x} + \frac{f(x+\Delta x, y+\Delta y) - f(x+\Delta x, y)}{\Delta y} \frac{\Delta y}{\Delta x} \right) \right\};$$

whence, if the partial derivatives exist and are continuous,*

$$(2)\qquad \frac{dz}{dx} = \lim_{\Delta x \to 0}\left[\frac{\Delta_x z}{\Delta x} + \frac{\Delta_y z}{\Delta y}\frac{\Delta y}{\Delta x}\right] = \frac{\partial z}{\partial x} + \frac{\partial z}{\partial y}\frac{dy}{dx},$$

or, multiplying both sides by $dx(=\Delta x)$,

$$(3)\qquad dz = \frac{\partial z}{\partial x}dx + \frac{\partial z}{\partial y}dy, \text{ since } dy = \frac{dy}{dx}dx,$$

where $dy = \phi(x)\,dx$. Since $\phi(x)$ is any function whatever, dy is really perfectly arbitrary. Hence (3) holds for any arbitrary values of dx and dy whatever, where $dz = (dz/dx)\,dx$ is defined by (2); dz is called the ***total differential of z***.

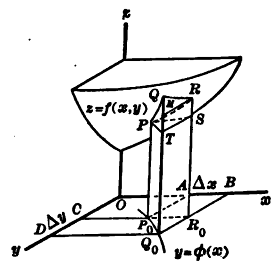

FIG. 78.

$PS = AB = \Delta x$
$ST = CD = \Delta y$
$SR = \Delta_x z = TM = R_0R - P_0P$
$MQ = \Delta_y z]_{x=x+\Delta x} = Q_0Q - R_0R$
$\Delta z = Q_0Q - P_0P = TQ = SR + MQ$
$\quad = \Delta_x z + \Delta_y z]_{x=x+\Delta x}$

These quantities are all represented in the figure geometrically: thus $\Delta z = \Delta_x z + \Delta_y z$ is represented by the geometric equation $TQ = SR + MQ$. It should be noticed that dz is the height of the plane drawn tangent to the surface at P, since $\partial z/\partial x$ and $\partial z/\partial y$ are the *slopes* of the sections of the surface by $y = y_P$ and $x = x_P$, respectively. [See also § 163.]

If the curve P_0Q_0 in the xy-plane is given in parameter form, $x = \phi(t)$, $y = \psi(t)$, we may divide both sides of (3) by dt and write

$$(4)\qquad \frac{dz}{dt} = \frac{\partial z}{\partial x}\frac{dx}{dt} + \frac{\partial z}{\partial y}\frac{dy}{dt},$$

since $dx \div dt = dx/dt$, $dy \div dt = dy/dt$.

*For a more detailed proof using the law of the mean, see Goursat-Hedrick, *Mathematical Analysis*, I, pp. 38–42.

159. Elementary Use. In elementary cases, many of which have been dealt with successfully before § 158, the use of the formulas (2), (3), and (4) of § 158 is quite self-evident.

EXAMPLE 1. The area of a cylindrical cup with no top is

$$(1) \qquad A = 2\pi rh + \pi r^2,$$

where h is the height, and r is the radius of the base. If the volume of the cup, $\pi r^2 h$, is known in advance, say $\pi r^2 h = 10$ (cubic inches), we actually do know a relation between h and r:

$$(2) \qquad h = \frac{10}{\pi r^2},$$

whence

$$(3) \qquad A = 2\pi r \frac{10}{\pi r^2} + \pi r^2 = \frac{20}{r} + \pi r^2$$

from which dA/dr can be found. We did precisely the same work in Ex. 26, p. 57. In fact even then we might have used (1) instead of (3), and we might have written

$$(4) \qquad \frac{dA}{dr} = 2\pi r\frac{dh}{dr} + 2\pi h + 2\pi r, \text{ or } dA = 2\pi r\, dh + (2\pi h + 2\pi r)\, dr,$$

where dh/dr is to be found from (2).

This is precisely what formula (2), § 158, does for us; for

$$(5) \qquad \frac{\partial A}{\partial r} = 2\pi h + 2\pi r, \quad \frac{\partial A}{\partial h} = 2\pi r,$$

$$\frac{dA}{dr} = (2\pi h + 2\pi r) + (2\pi r)\frac{dh}{dr}, \text{ or } dA = (2\pi h + 2\pi r)\, dr + 2\pi r\, dh.$$

We used just such equations as (4) to get the critical values in finding extremes for $dA/dr = 0$ at a critical point. We may now use (2), § 158, to find dA/dr; and the work is considerably shortened in some cases.

EXAMPLE 2. The derivative dy/dx can be found from (2), § 158, if we know that z is constant.

Thus in § 24, p. 39, we had the equation

$$(1) \qquad x^2 + y^2 = 1,$$

and we wrote:

$$(2) \qquad \frac{d(x^2+y^2)}{dx} = 2x + 2y\frac{dy}{dx} = \frac{d(1)}{dx} = 0,$$

whence we found

$$(3) \qquad x + y\frac{dy}{dx} = 0, \text{ or } \frac{dy}{dx} = -\frac{x}{y}.$$

This work may be thought of as follows:

Let $z = x^2 + y^2$; then

$$\frac{dz}{dx} = \frac{d(x^2+y^2)}{dx} = \frac{\partial z}{\partial x} + \frac{\partial z}{\partial y}\frac{dy}{dx} = 2x + 2y\frac{dy}{dx};$$

but $z = 1$ by (1) above; hence $dz/dx = 0$, and

$$2x + 2y\frac{dy}{dx} = 0, \text{ or } \frac{dy}{dx} = -\frac{x}{y}.$$

Thus the use of the formulas of § 158 is essentially ***not at all new;*** the preceding exercises and the work we have done in §§ 24, 29, etc., really employ the same principle. But the same facts appear in a new light by means of § 158; and the new formulas are a real assistance in many examples.

160. Small Errors. Partial Differentials. Another application closely allied to the work of § 145, p. 248, is found in the estimation of small errors.

EXAMPLE 1. The angle A of a right triangle ABC ($C = 90°$) may be computed by the formula

$$\tan A = \frac{a}{b}, \text{ or } A = \tan^{-1}\frac{a}{b},$$

where a, b, c are the sides opposite A, B, C. If an error is made in measuring a or b, the computed value of A is of course false. We may estimate the error in A caused by an error in measuring a, supposing temporarily that b is correct, by § 145; this gives approximately

$$\Delta_a A = \frac{\partial A}{\partial a}\Delta a = \frac{\frac{1}{b}}{1+\frac{a^2}{b^2}}\Delta a = \frac{b}{a^2+b^2}\Delta a,$$

where ∂ is used in place of d of § 145, since A really depends on b also, and we have simply supposed b constant temporarily. Likewise the error in A caused by an error in b is approximately,

$$\Delta_b A = \frac{\partial A}{\partial b}\Delta b = \frac{-\frac{a}{b^2}}{1+\frac{a^2}{b^2}}\Delta b = \frac{-a}{a^2+b^2}\Delta b.$$

If errors are possible in both measurements, the total error in A is, approximately, the sum of these two partial errors:

$$|\Delta A| \leqq |\Delta_a A| + |\Delta_b A| = \frac{b|\Delta a| + a|\Delta b|}{a^2+b^2}.$$

The methods of § 146, p. 251, give a means of finding how nearly correct these estimates of $\Delta_a A$, $\Delta_b A$, and ΔA are; in practice, such values as those just found serve as a guide, since it is usually desired only to give a general idea of the amounts of such errors.

This method is perfectly general. The differences in the value of a function $z = f(x, y)$ of two variables, x and y, which are caused by differences in the value of x alone, or of y alone, are denoted by $\Delta_x z$, $\Delta_y z$, respectively. The total difference in z caused by a change in both x and y is

$$\begin{aligned}\Delta z &= f(x+\Delta x, y+\Delta y) - f(x, y)\\ &= [f(x+\Delta x, y+\Delta y) - f(x+\Delta x, y)] + [f(x+\Delta x, y)\\ &\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad - f(x, y)]\\ &= \Delta_y z]_{x=x+\Delta x} + \Delta_x z,\end{aligned}$$

as in § 158. The differences $\Delta_x z$ and $\Delta_y z$ are, approximately,*

$$\Delta_x z = \frac{\partial z}{\partial x}\Delta x,\ \Delta_y z = \frac{\partial z}{\partial y}\Delta y;$$

whence, approximately,

$$\Delta z = \Delta_y z + \Delta_x z = \frac{\partial z}{\partial x}\Delta x + \frac{\partial z}{\partial y}\Delta y.$$

* More precisely, these errors are

$$\Delta_x z = \frac{\partial z}{\partial x}\cdot\Delta x + E'_2,\quad \Delta_y z = \left.\frac{\partial z}{\partial y}\right]_{x=x+\Delta x}\cdot\Delta y + E''_2,$$

where $|E'_2|$ and $|E''_2|$ are less than the maximum M_2 of the values of all of the second derivatives of z near (x, y) multiplied by $\overline{\Delta x}^2$, or $\overline{\Delta y}^2$, respectively (see §146). And since $\partial z/\partial y$ is itself supposed to be continuous, we may write

$$\Delta z = \frac{\partial z}{\partial x}\Delta x + \frac{\partial z}{\partial y}\Delta y + E_2,$$

where $|E_2|$ is less than $M_2(|\Delta x| + |\Delta y|)^2$. [Law of the Mean. Compare §146.]

The products $(\partial z/\partial x)\, dx$ and $(\partial z/\partial y)\, dy$ are often called the ***partial differentials*** of z, and are denoted by

$$\partial_x z = \frac{\partial z}{\partial x}\, dx, \ \partial_y z = \frac{\partial z}{\partial y}\, dy, \text{ whence } dz = \partial_x z + \partial_y z.$$

We have therefore, approximately,

$$\Delta z = \partial_x z + \partial_y z,$$

within an amount which can be estimated as in § 146 and in the preceding footnote.

Similar formulas give an estimate of the values of the changes in a function $u = f(x, y, z)$ of the variables x, y, z; we have, approximately,

$$\Delta_x u = \frac{\partial u}{\partial x}\Delta x, \quad \Delta_y u = \frac{\partial u}{\partial y}\Delta y, \quad \Delta_z u = \frac{\partial u}{\partial z}\Delta z,$$

$$\Delta u = \Delta_x u + \Delta_y u + \Delta_z u = \frac{\partial u}{\partial x}\Delta x + \frac{\partial u}{\partial y}\Delta y + \frac{\partial u}{\partial z}\Delta z,$$

within an amount which can be estimated as in the preceding footnote. The generalization to the case of more than three variables is obvious.

EXERCISES

Find dy/dx in each of the following implicit equations by method of Ex. 2, § 159:

1. $x^2 + 4y^2 = 1.$ **3.** $x^3 + y^3 - 3xy = 0.$

2. $7x^2 - 9y^2 = 36.$ **4.** $y^2(2a - x) = x^3.$

5. If A, B, C denote the angles, and a, b, c the sides opposite them, respectively, in a plane triangle, and if a, A, B are known by measurements, $b = a \sin B/\sin A$. Show that the error in the computed value of b due to an error da in measuring a is, approximately,

$$\partial_a b = \sin B \csc A\, da.$$

Likewise show that

$$\partial_A b = -a \sin B \csc A \operatorname{ctn} A\, dA, \text{ and } \partial_B b = a \cos B \csc A\, dB;$$

and the maximum total error is, approximately, $|db| \leqq |\partial_a b| + |\partial_A b| + |\partial_B b|$. Note that dA and dB are to be expressed in radian measure.

6. The measured parts of a triangle and their probable errors are

$$a = 100 \pm .01 \text{ ft.}, \quad A = 100° \pm 1', \quad B = 40° \pm 1'.$$

Show that the partial errors in the side b are

$$\partial_a b = \pm .007 \text{ ft.}, \qquad \partial_A b = \pm .003 \text{ ft.}, \qquad \partial_B b = \pm .023 \text{ ft.}$$

If these should all combine with like signs, the maximum total error would be

$$db = \pm .033 \text{ ft.}$$

7. If $a = 100$ ft., $B = 30°$, $A = 110°$, and each is subject to an error of 1%, find the per cent of error in b.

8. Find the partial and total errors in angle B, when

$$a = 100 \pm .01 \text{ ft.}, \quad b = 159 \pm .01 \text{ ft.}, \quad A = 30° \pm 1'.$$

9. The radius of the base and the altitude of a right circular cone being measured to 1%, what is the possible per cent of error in the volume? *Ans.* 3%.

10. The formula for index of refraction is $m = \sin i/\sin r$, i being the angle of incidence and r the angle of refraction. If $i = 50°$ and $r = 40°$, each subject to an error of 1%, what is m, and what its actual and its percentage error?

11. Water is flowing through a pipe of length L ft., and diameter D ft., under a head of H ft. The flow, in cubic feet per minute, is $Q = 2356\sqrt{\dfrac{HD^5}{L + 30D}}$. If $L = 1000$, $D = 2$, and $H = 100$, determine the change in Q due to an increase of 1% in H; in L; in D. Compare the partial differentials with the partial increments.

161. Envelopes. The straight line

$$(1) \qquad y = kx - k^2,$$

where k is a constant to which various values may be assigned, has a different position for each value of k. All the straight lines which (1) represents *may* be tangents to some one curve. If they are, the point P_k, (x, y) at which (1) is tangent to the curve, evidently depends on the value of k:

$$(2) \qquad x = \phi(k), \qquad y = \psi(k);$$

these equations may be considered to be the parameter equations of the required curve. The motive is to find the functions $\phi(k)$ and $\psi(k)$ if possible.

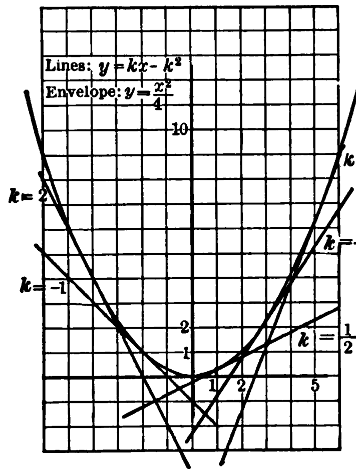

FIG. 79.

Since P_k *lies on* (1) *and on* (2), we may substitute from (2) in (1) to obtain:

(3) $\psi(k) = k\phi(k) - k^2,$

which must hold for all values of k. Moreover, *since* (1) *is tangent to* (2) at P_k, the values of dy/dx found from (1) and from (2) must coincide:

(4) $$k = \frac{dy}{dx}\bigg]_{\text{from (1)}} = \frac{dy}{dx}\bigg]_{\text{from (2)}} = \frac{\psi'(k)}{\phi'(k)}, \quad \text{or} \quad k\phi'(k) = \psi'(k).$$

To find $\phi(k)$ and $\psi(k)$ from the two equations (3) and (4), it is evident that it is expedient to differentiate both sides of (3) with respect to k:

(3 *) $$\psi'(k) = k\phi'(k) + \phi(k) - 2k;$$

this equation reduces by means of (4) to the form

(5) $$0 = 0 + \phi(k) - 2k, \quad \text{or} \quad \phi(k) = 2k,$$

and then (3) gives

(6) $$\psi(k) = k(2k) - k^2 = k^2.$$

Hence the parameter equations (2) of the desired curve are

(7) $$x = 2k, \quad y = k^2,$$

and the equation in usual form results by elimination of k:

(8) $$y = \frac{x^2}{4}.$$

It is easy to show that the tangents to (8) are precisely the straight lines (1).

The preceding method is perfectly general. Given any set of curves

$$(1)' \qquad F(x, y, k) = 0,$$

where k may have various values, a curve to which they are all tangent is called their envelope; its equations may be written

$$(2)' \qquad x = \phi(k),\ y = \psi(k);$$

whence by substitution in (1)',

$$(3)' \qquad F[\phi(k), \psi(k), k] = 0,$$

for all values of k. Differentiating (3)' with respect to k,

$$(3^*)' \qquad \frac{dF(x, y, k)}{dk} = \frac{\partial F}{\partial x}\frac{dx}{dk} + \frac{\partial F}{\partial y}\frac{dy}{dk} + \frac{\partial F}{\partial k} = 0.$$

Moreover, since (1)' is *tangent* to (2)',

$$(4)' \qquad -\frac{\partial F}{\partial x} \div \frac{\partial F}{\partial y} = \left.\frac{dy}{dx}\right]_{\text{from }(1)'} = \left.\frac{dy}{dx}\right]_{\text{from }(2)'} = \frac{dy}{dk} \div \frac{dx}{dk};$$

whence (3*)' reduces to the form

$$(5)' \qquad \frac{\partial F}{\partial k} = 0;$$

and then (3)' and (5)' may be solved as simultaneous equations to find $\phi(k)$ and $\psi(k)$ as in the preceding example.

The envelope may be found speedily by simply writing down the equations (1)' and (5)', and then eliminating k between them It is recommended very strongly that this should not be done until the student is familiar with the direct solution as shown in the preceding example.

162. Envelope of Normals. Evolute. If $y = f(x)$ is a given curve and if y_k and m_k respectively denote the ordinate and slope when $x = k$, the equation of any normal may be written

$$(1) \qquad y - y_k = -\frac{1}{m_k}(x - k),$$

or

$$F(x, y, k) = ym_k - y_k m_k + x - k = 0$$

Hence by (5′), § 161, we have, for the envelope of the system of lines (1) when k is regarded as a variable parameter,

(2) $$\frac{\partial F}{\partial k} = y \cdot b_k - y_k \cdot b_k - m_k \cdot m_k - 1 = 0.$$

(Remember that in forming $\partial F/\partial k$, x and y are regarded as constant, and only k, m_k, y_k, are regarded as variable. We have used b_k to stand for $\partial m_k/\partial k$.)

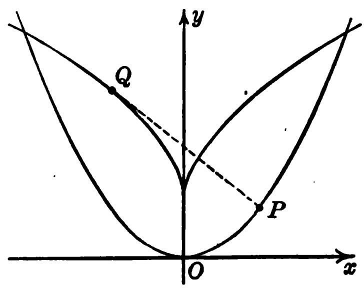

FIG. 80.

Solving (2) for y we have

(3) $$y = y_k + \frac{1 + m^2{}_k}{b_k}.$$

This value of y in (1) gives

(4) $$x = k - m_k \frac{1 + m^2{}_k}{b_k}.$$

Equations (3) and (4) are the parametric equations of the envelope of the system of normals (1), and are precisely equations (1) of § 98, with only a change of notation. Hence *the envelope of the systems of normals to a given curve is the evolute of that curve.*

EXERCISES

Find the envelopes of each of the following families of curves:

1. $y = 3kx - k^3$. *Ans.* $y^2 = 4x^3$.

2. $y = 4kx - k^4$. *Ans.* $y^3 = 27x^4$.

3. $y^2 = kx - k^2$. *Ans.* $y = \pm \frac{1}{2} x$.

4. $y = kx \pm \sqrt{1 + k^2}$. *Ans.* $x^2 + y^2 = 1$.

5. $y^2 = k^2 x - 2k$. *Ans.* $xy^2 = -1$.

6. $(x-k)^2+y^2=2k$. *Ans.* $y^2=2x+1$.

7. $4x^2+(y-k)^2=1-k^2$. *Ans.* $y^2+8x^2=2$.

8. $x\cos\theta+y\sin\theta=10$. *Ans.* $x^2+y^2=100$.

9. Show that the envelope of a family of circles through the origin with their centers on the parabola $y^2=2x$ is $y^2(x+1)+x^3=0$.

10. Show that the envelope of the family of straight lines $ax+by=1$ where $a+b=ab$, is the parabola $x^{1/2}+y^{1/2}=1$.

11. Show that the envelope of the family of parabolas represented by the equation $y=x\tan\alpha-mx^2\sec^2\alpha$ is $y=1/(4m)-mx^2$.

[NOTE. If $m=g/(2v_0^2)$, the given equation represents the path of a projectile fired from the origin with initial speed v_0 at an angle of elevation α.]

12. The lemniscate $(x^2+y^2)^2=a^2(x^2-y^2)$ may be written in the form $x=a\cos t\sqrt{\cos 2t}$; $y=a\sin t\sqrt{\cos 2t}$. Show that the evolute is $(x^{2/3}+y^{2/3})^2(x^{2/3}-y^{2/3})=4a^2/9$.

CHAPTER XVIII

CURVED SURFACES — CURVES IN SPACE

163. Tangent Plane to a Surface. Let P_0 be the point $(x_0\ y_0, z_0)$ on the surface $z = f(x, y)$. Let P_0T_1 be the tangent line at P_0 to the curve cut from the surface by the plane $y = y_0$ and P_0T_2 the tangent line to the curve cut from the surface by the plane $x = x_0$. The plane containing these two lines is the tangent plane to the surface at P_0.

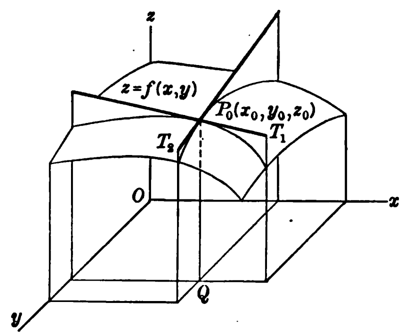

FIG. 81.

Since this plane goes through P_0, its equation can be thrown into the form

(1) $$z - z_0 = A(x - x_0) + B(y - y_0).$$

If we set $y = y_0$ we find the equation of P_0T_1 in the form:

(2) $$z - z_0 = A(x - x_0).$$

But, from § 28, p. 49, the equation of P_0T_1 may be written in the form:

(3) $$z - z_0 = \left.\frac{\partial f}{\partial x}\right]_0 (x - x_0).$$

Hence

(4) $$A = \left.\frac{\partial f}{\partial x}\right]_0; \text{ likewise } B = \left.\frac{\partial f}{\partial y}\right]_0.$$

Thus the ***equation of the tangent plane*** is

$$(5)\qquad z - z_0 = \frac{\partial f}{\partial x}\bigg]_0 (x - x_0) + \frac{\partial f}{\partial y}\bigg]_0 (y - y_0);$$

or, what is the same thing,

$$(6)\qquad z - z_0 = \frac{\partial z}{\partial x}\bigg]_0 (x - x_0) + \frac{\partial z}{\partial y}\bigg]_0 (y - y_0).$$

It is important to notice the great similarity between this equation and the equation

$$(7)\qquad dz = \frac{\partial z}{\partial x}\bigg]_0 dx + \frac{\partial z}{\partial y}\bigg]_0 dy,$$

of § 158. Indeed (7) expresses the fact that if dx, dy are measured parallel to the x and y axes from the point of tangency (x_0, y_0, z_0), dz represents the height of the tangent plane above (x_0, y_0, z_0). Equation (7) furnishes a good means of remembering (6).

164. Extremes on a Surface. If a function $z = f(x, y)$ is represented geometrically by a surface, it is evident that the extreme values of z are represented by the points on the surface which are the *highest*, or the *lowest*, points in their neighborhood:

(1) $f(x_0, y_0) > f(x_0 + h, y_0 + k)$, if $f(x_0, y_0)$ is a *maximum*,

(2) $f(x_0, y_0) < f(x_0 + h, y_0 + k)$, if $f(x_0, y_0)$ is a *minimum*,

for all values of h and k for which $h^2 + k^2$ is not zero and is not too large.

It is evident directly from the geometry of the figure that *the tangent plane at such a point is horizontal.*

This results also, however, from the fact that the section of the surface by the plane $x = x_0$ must have an extreme at (x_0, y_0); hence $[\partial f/\partial y]_0$, which is the slope of this section at $(x_0\, y_0)$, must be zero; likewise $[\partial f/\partial x]_0$, the slope of the

section through (x_0, y_0) by the plane $y = y_0$, must be zero. Hence equation (5), § 163, reduces to $z - z_0 = 0$ which is a horizontal plane.

A point at which the tangent plane is horizontal is called a *critical point* on the surface. The following cases may present themselves.

(1) *The surface may cut through its tangent plane; then there is **no extreme** at* (x_0, y_0).

This is what happens at a point on a surface of the saddleback type shown by a hyperbolic paraboloid at the origin; a homelier example is the depression between the knuckles of a clenched fist.

(2) *The surface may just touch its tangent plane along a whole line, but not pierce through; then there is what is often called a **weak extreme** at* (x_0, y_0); that is, $z = f(x, y)$ has the same value along a whole line that it has at (x_0, y_0), but otherwise $f(x, y)$ is less than [or greater than] $f(x_0, y_0)$.

This is what happens on the top of a surface which has a rim, such as the upper edge of a water glass, or the highest point of an anchor ring lying on its side. Most objects intended to stand on a table are provided with a rim on which to sit; they touch the table all along this rim, but do not pierce through the table.

(3) *The surface may touch its tangent plane only at the point* (x_0, y_0)*; then* $z = f(x, y)$ *is an **extreme** at* (x_0, y_0): a ***minimum,*** if the surface is wholly above the tangent plane near (x_0, y_0); a ***maximum,*** if the surface is wholly below.

The shape of the clenched fist gives many good illustrations of this type also. Examples of formal algebraic character occur below.

Example 1. For the elliptic paraboloid $z = x^2 + y^2$ the tangent plane at (x_0, y_0, z_0) is

$$z - z_0 = 2\,x_0\,(x - x_0) + 2\,y_0\,(y - y_0),$$

which is horizontal if $2\,x_0 = 2\,y_0 = 0$; this gives $x_0 = y_0 = z_0 = 0$, hence $(x = 0,\ y = 0)$ is the only *critical point.*

At ($x = 0$, $y = 0$), z has the value 0; for any other values of x and y, $z\,(= x^2 + y^2)$ is surely positive. It follows that z is a minimum at $x = 0$, $y = 0$.

EXAMPLE 2. In experiments with a pulley-block the weight w to be lifted and the pull p necessary to lift it were found in three trials to be (in pounds) ($p_1 = 5$, $w_1 = 20$), ($p_2 = 9$, $w_2 = 50$), ($p_3 = 15$, $w_3 = 90$). Assuming that $p = \alpha w + \beta$, find the values of α and β which make *the sum S of the squares of the errors least.* (Compare Ex. 37, p. 58.)

Computing p by the formula $\alpha w + \beta$, the three values are $p'_1 = 20\,\alpha + \beta$, $p'_2 = 50\,\alpha + \beta$, $p'_3 = 90\,\alpha + \beta$. Hence the sum of the squares of the errors is

$$\begin{aligned} S &= (p'_1 - p_1)^2 + (p'_2 - p_2)^2 + (p'_3 - p_3)^2 \\ &= (20\,\alpha + \beta - 5)^2 + (50\,\alpha + \beta - 9)^2 + (90\,\alpha + \beta - 15)^2. \end{aligned}$$

In order that S be a minimum, we must have

$$\frac{\partial S}{\partial \alpha} = 2\cdot[20\,(20\,\alpha + \beta - 5) + 50\,(50\,\alpha + \beta - 9) + 90\,(90\,\alpha + \beta - 15)] = 0.$$

$$\frac{\partial S}{\partial \beta} = 2\,[(20\,\alpha + \beta - 5) + (50\,\alpha + \beta - 9) + (90\,\alpha + \beta - 15)] = 0.$$

that is, after reduction,

$$\begin{aligned} 1100 + 16\,\beta - 190 &= 0, \\ 160\,\alpha + 3\,\beta - 29 &= 0, \end{aligned} \qquad \text{whence} \qquad \begin{aligned} \alpha &= \tfrac{106}{740} = .143, \\ \beta &= \tfrac{1500}{740} = 2.03. \end{aligned}$$

If the usual graph of the values of p and w is drawn, it will be seen that $p = \alpha w + \beta$ represents these values very well for $\alpha = .143$, $\beta = 2.03$ and it is evident from the geometry of the figure that these values render S a minimum, $S = .0545$; for any considerable increase in either α or β very evidently makes S increase. Since this is the only critical point, it surely corresponds to a minimum, for the function S has no singularities.

This conclusion can also be reached by thinking of S as represented by the heights of a surface over an $\alpha\beta$ plane, and considering the section of that surface by the tangent plane at the point just found as in Ex. 3 below; but in this problem the preceding argument is simpler.

It is customary to assume that the values of α and β which make S a minimum are the best compromise, or the "***most probable values***"; hence the most probable formula for p is $p = .143\,w + 2.03$.

The work based on more than three trials is quite similar; the only change being that S has n terms instead of 3 if n trials are made.

EXAMPLE 3. Find the most economical dimensions for a rectangular bin with an open top which is to hold 500 cu. ft. of grain.

Let x, y, h represent the width, length, and height of the bin, respectively. Then the volume is xyh; hence $xyh = 500$; and the total area z of the sides and bottom is

$$(a) \qquad z = xy + 2\,hy + 2\,hx = xy + \frac{1000}{x} + \frac{1000}{y}.$$

If this area (which represents the amount of material used) is to be a minimum, we must have

$$(b) \qquad \frac{\partial z}{\partial x} = y - \frac{1000}{x^2} = 0, \quad \frac{\partial z}{\partial y} = x - \frac{1000}{y^2} = 0.$$

Substituting from the first of these the value $y = 1000/x^2$ in the second, we find

$$(c) \qquad x - \frac{x^4}{1000} = 0, \text{ whence } x = 0, \text{ or } x = 10.$$

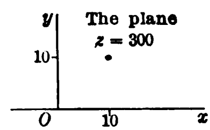

FIG. 82.

The value $x = 0$ is obviously not worthy of any consideration; but the value $x = 10$ gives $y = 1000/x^2 = 10$ and $h = 500/(xy) = 5$.

The value of z when $x = 10$, $y = 10$ is 300. If the equation (a) is represented graphically by a surface, the values of z being drawn vertical, the section of the surface by the plane $z = 300$ is represented by the equation

$$(d) \qquad xy + \frac{1000}{x} + \frac{1000}{y} = 300, \text{ or } x^2y^2 - 300\,xy + 1000\,(x + y) = 0.$$

This equation is of course satisfied by $x = 10$, $y = 10$. If we attempt to plot the curve near (10, 10), — for example, if we set $y = 10 + k$ and try to solve for x in the resulting equation:

$$(10 + k)^2\,x^2 - (300\,k + 2000)\,x + 1000\,(10 + k) = 0,$$

the usual rule for imaginary roots of any quadratic $ax^2 + bx + c = 0$ shows that

$$b^2 - 4\,ac = -\,1000\,k^2\,[4\,k + 30] < 0$$

for all values of k greater than $-\,7.5$. Hence it is impossible to find any other point on the curve near (10, 10). It follows that the horizontal tangent plane $z = 300$ cuts the surface in a single point; hence the surface lies entirely on one side of that tangent plane. Trial of any one convenient pair of values of x and y near (10, 10) shows that z is greater near (10, 10) than at (10, 10); hence the area z is a minimum when $x = 10$, $y = 10$, which gives $h = 5$.

165. Final Tests. Final tests to determine whether a function $f(x, y)$ has a maximum or a minimum or neither, are somewhat difficult to obtain in reliable form. Comparatively simple and natural examples are known which escape all set rules of an elementary nature.* (See Example 1 below.)

One elementary fact is often useful: if the surface has a maximum at (x_0, y_0), *every vertical section through* (x_0, y_0) *has a maximum there.* Thus any critical point (x_0, y_0) may be discarded if the section by the plane $x = x_0$ has no extreme at that point, or if it has the opposite sort of extreme to the section made by $y = y_0$.

EXAMPLE 1. The surface $z = (y - x^2)(y - 2x^2)$ has critical points where

$$\frac{\partial f}{\partial x} = -6xy + 8x^3 = 0, \quad \frac{\partial f}{\partial y} = 2y - 3x^2 = 0;$$

that is, the only critical point is $(x = 0, y = 0)$. The tangent plane at that point is $z = 0$. This tangent plane cuts the surface where

$$(y - x^2)(y - 2x^2) = 0;$$

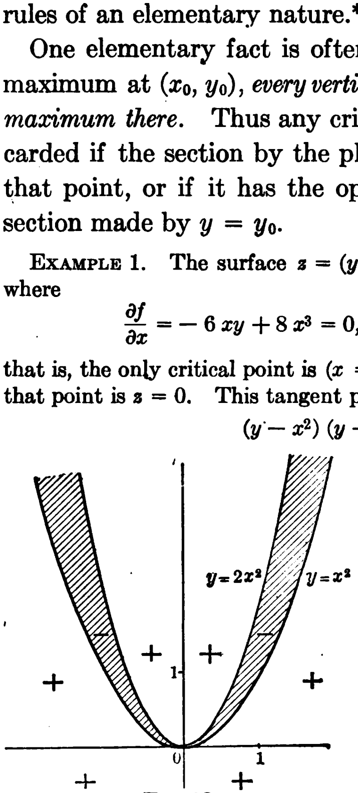

FIG. 83.

that is, along the two parabolas $y = x^2$, $y = 2x^2$. At $x = 0$, $y = 1$, the value of z is $+1$; hence z is positive for points (x, y) inside the parabola $y = 2x^2$. At $x = 1$, $y = 0$, the value of z is $+2$; hence z is positive for all points (x, y) outside the parabola $y = x^2$. At the point $x = 1$, $y = 1.5$, the value of z is $-.25$; hence z is negative between the two parabolas. It is evident, therefore, that z has no extreme at $x = 0$, $y = 0$.

A qualitative model of this extremely interesting surface can be made quickly by molding putty or plaster of paris in elevations in the

* For a detailed discussion, see Goursat-Hedrick, *Mathematical Analysis*, Vol. I, p. 118.

unshaded regions indicated above, with a depression in the shaded portion.

Another interesting fact is that every vertical section of this surface through (0, 0) has a minimum at (0, 0); this fact shows that the rule about vertical sections stated above cannot be reversed. Moreover, this surface eludes every other known elementary test except that used above.

EXERCISES

Find the equation of the tangent plane to each of the following surfaces at the point specified:

1. $z = x^2 + 9y^2$, (2, 1, 13). *Ans.* $z = 4x + 18y - 13$.

2. $z = 2x^2 - 4y^2$, (3, 2, 2). *Ans.* $z = 12x - 16y - 2$.

3. $z = xy$, (2, − 3, − 6). *Ans.* $3x - 2y + z = 6$.

4. $z = (x + y)^2$, (1, 1, 4). *Ans.* $4x + 4y - z = 4$.

5. $z = 2xy^2 + y^3$, (2, 0, 0) *Ans.* $z = 0$.

6–10. The straight line perpendicular to the tangent plane at its point of tangency is called the ***normal*** to the surface.

Find the normal to each of the surfaces in Exs. 1–5, at the point specified.

11. At what angle does the plane $x + 2y - z + 3 = 0$ cut the paraboloid $x^2 + y^2 = 4z$ at the point (6, 8, 25)?

12. Find the angle between the surfaces of Exs. 1 and 2 at the point $(\sqrt{13}, 1, 22)$.

Find the angle between each pair of surfaces in Exs. 1–5, at some one of their points of intersection, if they intersect.

13. Find the tangent plane to the sphere $x^2 + y^2 + z^2 = 25$ at the point (3, 4, 0); at $(2, 4, \sqrt{5})$.

14. At what angles does the line $x = 2y = 3z$ cut the paraboloid $y = x^2 + z^2$?

15. Find a point at which the tangent plane to the surface 1 is horizontal.

Draw the contour lines of the surface near that point and show whether the point is a minimum or a maximum or neither.

16. Proceed as in Ex. 15 for each of the surfaces of Exs. 2-5, and verify the following facts:

(**2**.) Horizontal tangent plane at (0, 0); no extreme.

(**3**.) Horizontal tangent plane at (0, 0); no extreme.

(**4**.) Horizontal tangent plane at every point on the line $x + y = 0$; weak minimum at each point.

(**5**.) Horizontal tangent plane at every point where $y = 0$; no extreme at any point.

Find the extremes, if any, on each of the following surfaces:

17. $z = x^2 + 4y^2 - 4x$. (Minimum at (2, 0, − 4).)

18. $z = x^3 - 3x - y^2$. (See *Tables*, Fig. I_1.)

19. $z = x^3 - 3x + y^2(x - 4)$. (See *Tables*, Fig. I_2.)

20. $z = [(x - a)^2 + y^2]\,[(x + a)^2 + y^2]$. (Similar to *Tables*, Fig. I_7.)

21. $z = x^3 - 6x - y^2$. (Draw auxiliary curve as for Fig. I_1.)

22. $z = x^3 - 4y^2 + xy^2$. (Draw auxiliary curve as for Fig. I_2.)

23. $z = x^3 + y^3 - 3xy$. (Draw by rotating xy-plane through $\pi/4$.)

24. Redetermine the values of α and β in Example 2, § 164, if the additional information ($p = 23$, $w = 135$) is given.

25. Find the values of u and v for which the expression

$$(a_1u + b_1v - c_1)^2 + (a_2u + b_2v - c_2)^2 + (a_3u + b_3v - c_3)^2$$

becomes a minimum. (Compare Ex. 24.)

26. Show that the most economical rectangular covered box is cubical.

27. Show that the rectangular parallelopiped of greatest volume that can be inscribed in a sphere is a cube.

[HINT. The equation of the sphere is $x^2 + y^2 + z^2 = 1$; one corner of the parallelopiped is at (x, y, z); then $V = 8xyz$, where $z = \sqrt{1 - x^2 - y^2}$.]

28. Show that the greatest rectangular parallelopiped which can be inscribed in an ellipsoid $x^2/a^2 + y^2/b^2 + z^2/c^2 = 1$ has a volume $V = 8abc/(3\sqrt{3})$.

29. The points (2, 4), (6, 7), (10, 9) do not lie on a straight line. Under the assumptions of § 164, show that the best compromise for a straight line which is experimentally determined by these values is $24y = 15x + 70$.

30. The linear extension E (in inches) of a copper wire stretched by a load W (in pounds) was found by experiment (Gibson) to be ($W = 10$, $E = .06$), ($W = 30$, $E = .17$), ($W = 60$, $E = .32$). Find values of α and β in the formula $E = \alpha W + \beta$ under the assumptions of § 164.

31. The readings of a standard gas meter S and that of a meter T being tested were found to be ($T = 4300$, $S = 500$), ($T = 4390$, $S = 600$), ($T = 4475$, $S = 700$). Find the most probable values in the equation $T = \alpha S + \beta$ and explain the meaning of α and of β.

32. The temperatures $\theta°$ C. at a depth d in feet below the surface of the ground in a mine were found to be $d = 100$ ft., $\theta = 15°.7$, $d = 200$ ft., $\theta = 16°.5$, $d = 300$ ft., $\theta = 17°.4$. Find an expression for the temperature at any depth.

33. The points (10, 3.1), (3.3, 1.6), (1.25, .7) lie very nearly on a curve of the form $\alpha/x + \beta/y = 1$. Use the *reciprocals* of the given values to find the most probable values of α and β.

34. The sizes of boiler flues and pressures under which they collapsed were found by Clark to be ($d = 30$, $p = 76$), ($d = 40$, $p = 45$), ($d = 50$, $p = 30$). These values satisfy very nearly an equation of the form $p = k \cdot d^n$ or $\log p = n \log d + \log k$, where d is the diameter in inches, and p is the pressure in pounds per square inch. Using the logarithms of the given numbers, find the most probable values for n and $\log k$.

166. Tangent Planes. Implicit Forms. If the equation of a surface is given in *implicit form*, $F(x, y, z) = 0$, taking the total differential we find:

$$(1) \qquad \frac{\partial F}{\partial x}dx + \frac{\partial F}{\partial y}dy + \frac{\partial F}{\partial z}dz = 0.$$

But, by virtue of $F(x, y, z) = 0$, any one of the variables, say z, is a function of the other two; hence

$$(2) \qquad dz = \frac{\partial z}{\partial x}dx + \frac{\partial z}{\partial y}dy.$$

Putting this in the total differential above and rearranging:

$$(3) \qquad \left(\frac{\partial F}{\partial x} + \frac{\partial F}{\partial z}\frac{\partial z}{\partial x}\right)dx + \left(\frac{\partial F}{\partial y} + \frac{\partial F}{\partial z}\frac{\partial z}{\partial y}\right)dy = 0.$$

But dx and dy are independent arbitrary increments of x and of y; and since the equation is to hold for all their possible pairs of values, the coefficients of dx and dy must vanish separately. This gives

$$(4) \qquad \frac{\partial z}{\partial x} = -\frac{\partial F/\partial x}{\partial F/\partial z}, \quad \frac{\partial z}{\partial y} = -\frac{\partial F/\partial y}{\partial F/\partial z}.$$

Substituting these values in the equation of the tangent plane, and clearing of fractions, we obtain

$$(5) \qquad \left.\frac{\partial F}{\partial x}\right]_0 (x - x_0) + \left.\frac{\partial F}{\partial y}\right]_0 (y - y_0) + \left.\frac{\partial F}{\partial z}\right]_0 (z - z_0) = 0,$$

the equation of the tangent plane at (x_0, y_0, z_0) to the surface $F(x, y, z) = 0$.

167. Line Normal to a Surface. The direction cosines of the tangent plane to a surface whose equation is given in the *explicit form* $z = f(x, y)$ are proportional (§ 163) to

$$(1) \qquad \partial z/\partial x]_0, \quad \partial z/\partial y]_0, \text{ and } -1.$$

Hence the *equations of the normal* at (x_0, y_0, z_0) are

$$(2) \qquad \frac{x - x_0}{\partial z/\partial x]_0} = \frac{y - y_0}{\partial z/\partial y]_0} = \frac{z - z_0}{-1}.$$

The direction cosines of a surface whose equation is given in the *implicit form* $F(x, y, z) = 0$ are proportional to

$$(3) \qquad \partial F/\partial x]_0, \quad \partial F/\partial y]_0, \quad \partial F/\partial z]_0,$$

so that the equations of the normal to this surface are

$$(4) \qquad \frac{x - x_0}{\partial F/\partial x]_0} = \frac{y - y_0}{\partial F/\partial y]_0} = \frac{z - z_0}{\partial F/\partial z]_0}.$$

168. Parametric Forms of Equations. A surface S may also be represented by expressing the coordinates of any point on it in terms of two auxiliary variables or parameters:

$$[S] \qquad x = f(u, v), \quad y = \phi(u, v), \quad z = \psi(u, v).$$

If we eliminate u and v between these equations, we obtain the equation of the surface in the form $F(x, y, z) = 0$.

Similarly a curve C may be represented by giving x, y, z in terms of a single auxiliary variable or parameter t:

$$[C] \qquad x = f(t), \; y = \phi(t), \; z = \psi(t).$$

The elimination of t from each of two pairs of these equations gives the equations of two surfaces on each of which the curve lies. In particular, taking $t = x$ gives the curve as the intersection of the projecting cylinders:

$$[P] \qquad y = \phi(x), \qquad z = \psi(x).$$

If, in the parametric equations of a surface, one parameter (say u) is kept fixed while the other varies, a space-curve is described which lies on the surface. Now if u varies, this curve varies as a whole and describes the surface. The curve on which u keeps the value k is called the curve $u = k$. Similarly, keeping v fixed while u varies gives a curve $v = k'$. The intersection of a curve $u = k$ with a curve $v = k'$ gives one or more points (k, k') on the surface. The numbers k, k' are called the **curvilinear coordinates** of points on the surface.

Simple examples of such coordinates are the ordinary rectangular coordinate system and the polar coordinate system in a plane. Thus (2, 3) means the point at the intersection of the lines $x = 2$, $y = 3$ of the plane; in polar coordinates, (5, 30°) means the point at the intersection of the circle $r = 5$ with the line $\theta = 30°$.

Example 1. The equations of the plane $x + y + z = 1$ may be written, in the parametric form:

$$x = u, \qquad y = v, \qquad z = 1 - u - v.$$

Let the student draw a figure from these equations by inserting arbitrary values of u and v and finding associated values of x, y, z. Another set of parameter equations which represent the same plane is

$$x = u + v, \qquad y = u - v, \qquad z = 0 - 2u + 1.$$

Thus several different sets of parameter equations may represent the same surface.

In the first form, put $u = k$. Then, as v varies, we obtain the straight line

$$x = k, \qquad y = v, \qquad z = 1 - k - v,$$

which lies in the given plane. As k varies this line varies; its different positions map out the entire plane. Likewise, $v = k'$ is a line varying with k' and describing the plane. The intersection of two of these lines, one from each system, is point (k, k') of the plane.

EXAMPLE 2. The sphere $x^2 + y^2 + z^2 = a^2$ may be represented by the equations:

$$x = a \sin \phi \cos \theta, \qquad y = a \sin \phi \sin \theta, \qquad z = a \cos \phi.$$

Here the parameters ϕ and θ are respectively the co-latitude and the longitude. Thus $\phi = k$ is a parallel of latitude; $\theta = k'$ is a meridian; and their intersection (k, k') is a point of co-latitude k and longitude k'. [If a is allowed to vary, the equations of this example define ***polar coordinates in space;*** but $90° - \phi$ is often used in place of ϕ.]

EXAMPLE 3. The equations

$$x = a \cos t, \qquad y = a \sin t, \qquad z = bt,$$

represent a space curve, namely a ***helix*** drawn on a cylinder of radius a with its axis along the z-axis. The total rise of the curve during each revolution is $2\pi b$.

If a is replaced by a variable parameter u, the helix varies with u, and describes the surface

$$x = u \cos t, \qquad y = u \sin t, \qquad z = bt,$$

which is called a ***helicoid.*** The blade of a propeller screw is a piece of such a surface.

169. Tangent Planes and Normals. Parameter Forms.

When a surface is given by means of *parametric equations,*

(1) $$x = f(u, v), \qquad y = \phi(u, v), \qquad z = \psi(u, v),$$

the equation of the tangent plane is found as follows. Elimination of u and v would give the equation in the implicit form $F(x, y, z) = 0$. If the parametric values of x, y, z are substituted in this equation, the resulting equation is identically true, since it must hold for all values of the independent parameters u, v; hence

(2) $$\frac{\partial F}{\partial u} = 0, \text{ and } \frac{\partial F}{\partial v} = 0,$$

that is

(3) $$\frac{\partial F}{\partial x}\frac{\partial x}{\partial u} + \frac{\partial F}{\partial y}\frac{\partial y}{\partial u} + \frac{\partial F}{\partial z}\frac{\partial z}{\partial u} = 0, \quad \frac{\partial F}{\partial x}\frac{\partial x}{\partial v} + \frac{\partial F}{\partial y}\frac{\partial y}{\partial v} + \frac{\partial F}{\partial z}\frac{\partial z}{\partial v} = 0.$$

Solving these, we find:

$$(4)\qquad \frac{\partial F}{\partial x} : \frac{\partial F}{\partial y} : \frac{\partial F}{\partial z} = \begin{vmatrix} \frac{\partial y}{\partial u} & \frac{\partial z}{\partial u} \\ \frac{\partial y}{\partial v} & \frac{\partial z}{\partial v} \end{vmatrix} : \begin{vmatrix} \frac{\partial z}{\partial u} & \frac{\partial x}{\partial u} \\ \frac{\partial z}{\partial v} & \frac{\partial x}{\partial v} \end{vmatrix} : \begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} \end{vmatrix};$$

hence the equation of the tangent plane is

$$(x-x_0)\begin{vmatrix} \frac{\partial y}{\partial u} & \frac{\partial z}{\partial u} \\ \frac{\partial y}{\partial v} & \frac{\partial z}{\partial v} \end{vmatrix}_0 + (y-y_0)\begin{vmatrix} \frac{\partial z}{\partial u} & \frac{\partial x}{\partial u} \\ \frac{\partial z}{\partial v} & \frac{\partial x}{\partial v} \end{vmatrix}_0 + (z-z_0)\begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} \end{vmatrix}_0 = 0;$$

while the equations of the normal are

$$\frac{x-x_0}{\begin{vmatrix} \frac{\partial y}{\partial u} & \frac{\partial z}{\partial u} \\ \frac{\partial y}{\partial v} & \frac{\partial z}{\partial v} \end{vmatrix}_0} = \frac{y-y_0}{\begin{vmatrix} \frac{\partial z}{\partial u} & \frac{\partial x}{\partial u} \\ \frac{\partial z}{\partial v} & \frac{\partial x}{\partial v} \end{vmatrix}_0} = \frac{z-z_0}{\begin{vmatrix} \frac{\partial x}{\partial u} & \frac{\partial y}{\partial u} \\ \frac{\partial x}{\partial v} & \frac{\partial y}{\partial v} \end{vmatrix}_0}.$$

EXERCISES

1. Determine the tangent plane and the normal to the ellipsoid $x^2 + 4y^2 + z^2 = 36$ at the point (4, 2, 2), first by solving for z, by the methods of § 163; then, without solving for z, by the methods of §§ 166–167.

Determine the tangent planes and the normals to each of the following surfaces, at the points specified:

2. $x^2 + y^2 + z^2 = a^2$ at (x_0, y_0, z_0).

3. $x^2 - 4y^2 + z^2 = 36$ at (6, 1, 2).

4. $x^2 - 4y^2 - 9z^2 = 36$ at (7, 1, 1).

5. $x^2 + y^2 - z^2 = 0$ at (3, 4, 5).

6. $x^3 + x^2y - 2z^2 = 0$ at (1, 1, − 1).

7. $z^2 = e^{x+y}$ at (0, 2, c).

8. Find the angle between the tangent planes to the ellipsoid $4x^2 + 9y^2 + 36z^2 = 36$ at the points $(2, 1, z_0)$ and $(-1, -1, z_1)$.

9. At what angle does the z-axis cut the surface $z^2 = e^{x-y}$?

10. Obtain the equation of the tangent plane to the helicoid

$$x = u \cos v, \qquad y = u \sin v, \qquad z = v,$$

at the point $u = 1$, $v = \pi/4$.

11. Taking the equations of a sphere in terms of the latitude and longitude (Example 2, § 168), find the equation of its tangent plane and the equations of the normal at a point where $\theta = \phi = 45°$; at a point where $\theta = 60°$, $\phi = 30°$.

12. Eliminate u and v from the equations $x = u + v$, $y = u - v$, $z = uv$, to obtain an equation in x, y, and z. Find the equation of the tangent plane at a point where $u = 3$, $v = 2$, by the methods of § 166; then by the methods of § 169 directly from the given equations.

13. Write the equation of the tangent plane to the surface used in Ex. 7 at any point (x_0, y_0, z_0). At what point is the tangent plane horizontal? Is z an extreme at that point?

Proceed as in Ex. 7 for each of the following surfaces:

14. $x = r \cos \theta$, $y = r \sin \theta$, $z = r$, at $r = 2$, $\theta = \pi/4$.

15. $x = \dfrac{uv + 1}{u + v}$, $y = \dfrac{u - v}{u + v}$, $z = \dfrac{uv - 1}{u + v}$, at $u = 2$, $v = -1$.

16. $x = -3u + 2v$, $y = 2u - v$, $z = e^{u+v}$, at (u_0, v_0).

17. $x = 2 \cos \theta \cos \phi$, $y = 3 \cos \theta \sin \phi$, $z = \sin \theta$, at $\theta = \phi = \pi/4$.

18. The surfaces $z = x^2 - 4y^2$ and $z = 6x$ intersect in a curve, whose equations are the two given equations. Find the tangent line to this curve at the point (8, 2, 48) by first finding the tangent planes to each of the surfaces at that point; the line of intersection of these planes is the required line.

19. Find the tangent line to the curve defined by the two equations $16x^2 - 3y^2 = 4z$ and $9x^2 + 3y^2 - z^2 = 20$ at (1, 2, 1).

170. Area of a Curved Surface. Let S be a portion of a curved surface and R its projection on the xy-plane. In R take an element $\Delta x \Delta y$ and on it erect a prism cutting an element ΔS out of S. At any point of ΔS, draw a tangent plane. The prism cuts from this an element ΔA. The smaller $\Delta x \, \Delta y$ (and therefore ΔS) becomes, the more nearly will the ratio $\Delta A / \Delta S$ approach unity, since we assume that the limit of this ratio is 1.

Suppose now that the area R is all divided up into elements $\Delta x \Delta y$ and that on each a prism is erected. The area S will thus be divided up into elements ΔS and there will be cut from the tangent plane at a point of each an element ΔA. One thus gets

(1) $$S = \lim_{\substack{\Delta x \to 0 \\ \Delta y \to 0}} \sum \Delta A.$$

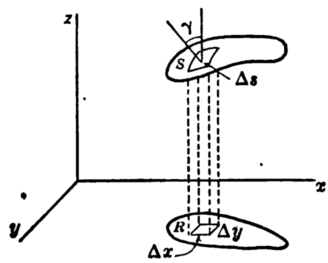

FIG. 84.

But if γ is the acute angle that the normal to any ΔA makes with the z-axis, we have

(2) $$\Delta A = \sec \gamma \, \Delta x \, \Delta y;$$

hence

(3) $$S = \lim_{\substack{\Delta x \to 0 \\ \Delta y \to 0}} \sum \Delta A = \lim_{\substack{\Delta x \to 0 \\ \Delta y \to 0}} \sum (\sec \gamma \, \Delta x \, \Delta y) = \iint_R \sec \gamma \, dx \, dy.$$

Of course $\sec \gamma$ is a variable to be expressed in terms of x and y from the equation of the surface. The limits of integration to be inserted are the same as if the area of R were to be found by means of the integral

$$\iint dx \, dy.$$

If the surface doubles back on itself, so that the projecting prisms cut it more than once, it will usually be best to calculate each piece separately.

When the equation of the surface is given in the form $z = f(x, y)$, the direction cosines of the normal are given by

$$\cos \alpha : \cos \beta : \cos \gamma = \frac{\partial z}{\partial x} : \frac{\partial z}{\partial y} : -1.$$

Taking $\cos \gamma$ positive, that is γ acute, we may write

(4) $$\sec \gamma = \sqrt{\left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2 + 1},$$

and $$S = \iint \sqrt{\left(\frac{\partial z}{\partial x}\right)^2 + \left(\frac{\partial z}{\partial y}\right)^2 + 1} \, dx \, dy.$$

The determination of $\sec \gamma$, when the surface is given in the form $F(x, y, z) = 0$, is performed by straightforward transformations similar to those used in §§ 167-169; they are left to the student.

EXERCISES

1. Calculate the area of a sphere by the preceding method.

2. A square hole is cut centrally through a sphere. How much of the spherical surface is removed?

3. A cylinder intersects a sphere so that an element of the cylinder coincides with a diameter of the sphere. If the diameter of the cylinder equals the radius of the sphere, what part of the spherical surface lies within the cylinder?

4. How much of the surface $z = xy$ lies within the cylinder $x^2 + y^2 = 1$?

5. How much of the conical surface $z^2 = x^2 + y^2$ lies above a square in the xy-plane whose center is the origin?

6. Show that if the region R of § 170 be referred to ordinary polar coordinates, $\Delta A = r \sec \gamma \, \Delta r \, \Delta\theta$, approximately. (See § 92, p. 149.)

7. Using the result of Ex. 6, show that $S = \int\int r \sec \gamma \, dr \, d\theta$.

8. Show that, for a surface of revolution formed by revolving a curve whose equation is $z = f(x)$ about the z-axis,

$$\sec \gamma = \sqrt{1 + [df(r)/dr]^2}, \text{ where } r = \sqrt{x^2 + y^2}.$$

9. By means of Exs. 7, 8, show that the area of the surface of revolution mentioned in Ex. 8 is

$$S = \int_0^a \int_0^{2\pi} r \sqrt{1 + \left[\frac{df(r)}{dr}\right]^2} dr \, d\theta = 2\pi \int_0^a r \sqrt{1 + \left[\frac{df(r)}{dr}\right]^2} dr,$$

where a is the value of r at the end of the arc of the generating curve.

10. Compute the area of a sphere by the method of Ex. 9.

11. Find the area of the portion of the paraboloid of revolution formed by revolving the curve $z^2 = 2mx$ about the x axis, from $x = 0$ to $x = k$.

12. Show that the area of the surface of an ellipsoid of revolution is $2\pi b\,[b + (a/e)\sin^{-1} e]$, where a and b are the semiaxes and e the eccentricity, of the generating ellipse.

13. Show that the area generated by revolving one arch of a cycloid about its base is $64\,\pi a^2/3$.

14. Show that the area of the surface generated by revolving the curve $x^{2/3} + y^{2/3} = a^{2/3}$ about one of the axes is $12\,\pi a^2/5$.

171. Tangent to a Space Curve. Let the equation of the curve be given in parametric form $x = f(t)$, $y = \phi(t)$, $z = \psi(t)$. Let $P_0 = (x_0, y_0, z_0)$ be the point on the curve where $t = t_0$. Let Q be a neighboring point on the curve where $t = t_0 + \Delta t$.

The direction cosines of the secant P_0Q are proportional to $\Delta x/\Delta t$, $\Delta y/\Delta t$, $\Delta z/\Delta t$; hence its equations are

$$(1)\quad \frac{x - x_0}{\Delta x/\Delta t} = \frac{y - y_0}{\Delta y/\Delta t} = \frac{z - z_0}{\Delta z/\Delta t}.$$

As $\Delta t \to 0$, these become

$$(2)\quad \frac{x - x_0}{dx/dt]_0} = \frac{y - y_0}{dy/dt]_0} = \frac{z - z_0}{dz/dt]_0},$$

the equations of the tangent at the point P_0.

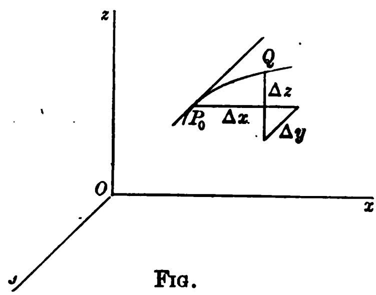

FIG.

If the curve is given as the intersection of two projecting cylinders $y = f(x)$, $z = \phi(x)$, we may join to these the third equation $x = x$, thus conceiving of x, y, and z as all expressed in terms of x. The equations of the tangent then become

$$(3)\qquad \frac{x - x_0}{1} = \frac{y - y_0}{dy/dx]_0} = \frac{z - z_0}{dz/dx]_0}.$$

If the curve is given as the intersection of two surfaces, $f(x, y, z) = 0$, $F(x, y, z) = 0$, and if we think of x, y, z as depending upon a parameter t, we find

$$\frac{df}{dt} = \frac{\partial f}{\partial x}\frac{dx}{dt} + \frac{\partial f}{\partial y}\frac{dy}{dt} + \frac{\partial f}{\partial z}\frac{dz}{dt} = 0,$$

and

$$\frac{dF}{dt} = \frac{\partial F}{\partial x}\frac{dx}{dt} + \frac{\partial F}{\partial y}\frac{dy}{dt} + \frac{\partial F}{\partial z}\frac{dz}{dt} = 0.$$

From these equations we obtain $dx/dt : dy/dt : dz/dt$, and we may write the equations of the tangent at P_0 in the form:

$$\frac{x - x_0}{\begin{vmatrix} \frac{\partial f}{\partial y} & \frac{\partial f}{\partial z} \\ \frac{\partial F}{\partial y} & \frac{\partial F}{\partial z} \end{vmatrix}_0} = \frac{y - y_0}{\begin{vmatrix} \frac{\partial f}{\partial z} & \frac{\partial f}{\partial x} \\ \frac{\partial F}{\partial z} & \frac{\partial F}{\partial x} \end{vmatrix}_0} = \frac{z - z_0}{\begin{vmatrix} \frac{\partial f}{\partial x} & \frac{\partial f}{\partial y} \\ \frac{\partial F}{\partial x} & \frac{\partial F}{\partial y} \end{vmatrix}_0}.$$

172. Length of a Space Curve. The length of the chord joining two points t and $t + \Delta t$ of the curve

$$(1)\qquad x = f(t),\ y = \phi(t),\ z = \psi(t),$$

is $\Delta c = \sqrt{\Delta x^2 + \Delta y^2 + \Delta z^2}$, or,

$$\Delta c = \sqrt{\frac{\Delta x^2}{\Delta t^2} + \frac{\Delta y^2}{\Delta t^2} + \frac{\Delta z^2}{\Delta t^2}}\,\Delta t. \tag{2}$$

Defining the length of a curve between two points as the limit of the sum of the inscribed chords, we find for that length:

$$s = \lim_{\Delta t \to 0} \sum \Delta c = \int_{t=t_0}^{t=t_1} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2 + \left(\frac{dz}{dt}\right)^2}\, dt. \tag{3}$$

EXERCISES

1. At what angle does a straight line joining the earth's South pole with a point in 40° North latitude cut the 40th parallel?

2. At what angle does the helix $x = 2\cos\theta$, $y = 2\sin\theta$, $z = \theta$, cut the sphere $x^2 + y^2 + z^2 = 9$?

3. Find the angle of intersection of the ellipse and parabola that are cut from the cone $z^2 = x^2 + y^2$ by the planes $2z = 1 - x$ and $z = 1 + x$ respectively.

4. Show that the curves of intersection of the three surfaces

$$z = y,\ x^2 = y^2 + z^2,\ x^2 + y^2 + z^2 = 1,$$

cut each other mutually at right angles.

5. Show the same for the curves of intersection of the surfaces

$$4x^2 + 9y^2 + 36z^2 = 36,\ 3x^2 + 6y^2 - 6z^2 = 6,\ 10x^2 - 15y^2 - 6z^2 = 30.$$

6. Calculate the length of the curve $x = t$, $y = t^2$, $z = 2t^{3/2}$, from $t = 0$ to $t = 1$.

7. Find the length of the helix $x = a\cos\theta$, $y = a\sin\theta$, $z = b\theta$, from $\theta = \theta_0$ to $\theta = \theta_1$. What is the length of one turn?

8. Find the length of the curve $x = \sin z$, $y = \cos z$, from $(1, 0, \pi/2)$ to $(0, -1, \pi)$.

GENERAL REVIEW EXERCISES

[The exercises marked with an asterisk are of more than usual difficulty. Some of them contain new concepts of value for which it is hoped that time may be found. Those of the greatest theoretical value are marked †.

Attention is called to the reviews of double and triple integration.]

1. Given $u = xy$, $x = r\cos\theta$, $y = r\sin\theta$, find $\partial u/\partial r$ and $\partial u/\partial\theta$, first by actually expressing u in terms of r and θ; then directly from the given equations.

2. Proceed as in Ex. 1 for the function $u = \tan^{-1}(y/x)$.

3. Given $u = r^2e^{2\theta}$, $x = r\cos\theta$, $y = r\sin\theta$, find $\partial u/\partial x$ and $\partial u/\partial y$, first by expressing u in terms of x and y; then directly from the given equations.

[HINT. In the second part, it is convenient here to solve the last two equations for r and θ in terms of x and y. But see Ex. 4.]

4.* If $x = r\cos\theta$ and $y = r\sin\theta$, show by differentiation that

$$\frac{\partial x}{\partial x} = 1 = \frac{\partial r}{\partial x}\cos\theta - r\sin\theta\,\frac{\partial\theta}{\partial x},\quad\text{and}\quad \frac{\partial y}{\partial x} = 0 = \frac{\partial r}{\partial x}\sin\theta + r\cos\theta\,\frac{\partial\theta}{\partial x}.$$

Solve these equations for $\partial r/\partial x$ and $\partial\theta/\partial x$, and show that $\partial u/\partial x$ may be found in Ex. 3 by means of the equation

$$\frac{\partial u}{\partial x} = \frac{\partial u}{\partial r}\frac{\partial r}{\partial x} + \frac{\partial u}{\partial\theta}\frac{\partial\theta}{\partial x}.$$

5.* If, in general, u is a function of the two variables (r, θ), show that the last equation in Ex. 4 holds true. Find a similar equation for $\partial u/\partial y$, and evaluate $\partial u/\partial y$ in Ex. 3 by means of it.

6.*† If u is a function of any two variables p and q, and if p and q are given in terms of x and y by two equations $x = f(p, q)$, $y = \phi(p, q)$, obtain $\partial u/\partial x$ and $\partial u/\partial y$ by a process analogous to that of Exs. 4, 5.

Proceed as in Ex. 3, by the methods of Exs. 4, 5, in each of the following cases:

7. $u = r^2 - \cos^2\theta$. **8.** $u = re^{\theta^2}$. **9.** $u = \theta\log r$.

10. Find the volume of that portion of a sphere of radius 4 ft. which is bounded by two parallel planes at distances 2 ft. and 3 ft., respectively, from the center, on the same side of the center.

11. Determine the position of the center of mass of the solid described in Ex. 10.

12. What is the nature of the field of integration in the integral

$$\int_0^{a/\sqrt{2}}\int_x^{\sqrt{a^2-x^2}} f(x, y)\,dy\,dx?$$

Show that the same integral may be written in the form

$$\int_0^{a/\sqrt{2}}\int_0^{x} f(x, y)\,dy\,dx + \int_{a/\sqrt{2}}^{a}\int_0^{\sqrt{a^2-y^2}} f(x, y)\,dx\,dy.$$

13. Find the volume cut from the sphere $x^2 + y^2 + z^2 = a^2$ by the cylinder $x^2 + y^2 - ax = 0$.

14. Find the volume cut from the sphere $x^2 + y^2 + z^2 = a^2$ by the cone $(x - a)^2 + y^2 - z^2 = 0$.

15. Show that the surface of a zone of a sphere depends only upon the radius of the sphere and the height $b - a$ of the zone, where the bounding planes are $z = a$ and $z = b$.

16. Find the area of that part of the surface $k^2z = xy$ within the cylinder $x^2 + y^2 = k^2$.

17. Find the center of gravity of the portion of the surface described in Ex. 16, when $k = 1$.

18. Find the moment of inertia about its edge, of a wedge whose cross section, perpendicular to the edge, is a sector of a circle of radius 1 and angle 30°, if the length of the edge is 1, and the density is 1.

19. The thrust due to water flowing against an element of a surface is proportional to the area of the element and to the square of the component of the speed perpendicular to the element. Show that the total thrust on a cone whose axis lies in the direction of the flow is $k\pi r^3v^2/(r^2 + h^2)^{\frac{1}{2}}$.

20. Calculate the total thrust due to water flowing against a segment of a paraboloid of revolution whose axis lies in the direction of the flow. (See Ex. 19.)

21. Show that the thrust due to water flowing against a sphere is $2\,k\pi r^2v^2/3$. Compare with the thrust due to the flow normally against a diametral plane of this sphere.

22. Find the critical points, if any exist, for the surface $z = x^2 + 2\,y^2 - 4\,x - 4\,y + 10$. Is the value of z an extreme at that point? Draw the contour lines near the point.

23. Determine the greatest rectangular parallelopiped which can be inscribed in a sphere of radius a.

24. The volume of CO_2 dissolved in a given amount of water at temperature θ is

θ	0	5	10	15,
v	1.80	1.45	1.18	1.00.

Determine the most probable relation of the form $v = a + b\theta$.

25. Determine the most probable relation of the form $S = a + b\,P^2$ from the data:

P	550	650	750	850,
S	26	35	52	70.

26. Determine the most probable relation of the form $y = ae^{bx}$ from the data:

$$\begin{cases} x & 1 & 2 & 3 & 4, \\ y & .74 & .27 & .16 & .04. \end{cases}$$

27. The barometric pressure P (inches) at height H (thousands feet)

$$\begin{cases} P & 30 & 28 & 26 & 24 & 22 & 20 & 18 & 16, \\ H & 0 & 1.8 & 3.8 & 5.9 & 8.1 & 10.5 & 13.2 & 16.0. \end{cases}$$

Determine the most probable values of the constants in each of the assumed relations: (*a*) $H = a + bP$; (*b*) $H = a + bP + cP^2$; (*c*) $H = a + b \log P$ or $P = Ae^{BH}$. Which is the best approximation?

28. † If the observed values of one quantity y are m_1, m_2, m_3, corresponding to values l_1, l_2, l_3 of a quantity x on which y depends, and if $y = ax + b$, show that the sum

$$S = (al_1 + b - m_1)^2 + (al_2 + b - m_2)^2 + (al_3 + b - m_3)^2$$

is least when

$$\begin{cases} l_1 (al_1 + b - m_1) + l_2 (al_2 + b - m_2) + l_3 (al_3 + b - m_3) = 0, \\ \quad (al_1 + b - m_1) + \quad (al_2 + b - m_2) + \quad (al_3 + b - m_3) = 0; \end{cases}$$

that is, when

$$a \cdot \sum l_1^2 + b \cdot \sum l_1 - \sum m_1 l_1 = 0 \text{ and } a \cdot \sum l_1 + 3b - \sum m_1 = 0,$$

or

$$a = \frac{3\sum m_1 l_1 - \sum m_1 \cdot \sum l_1}{3\sum l_1^2 - \left[\sum l_1\right]^2}, \quad b = \frac{\sum l_1^2 \cdot \sum m_1 - \sum m_1 l_1 \cdot \sum l_1}{3\sum l_1^2 - \left[\sum l_1\right]^2}$$

where $\sum$ indicates the sum of such terms as that which follows it.

[THEORY OF LEAST SQUARES.]

29. Show that the equation of the tangent plane to $2z = x^2 + y^2$ at (x_0, y_0) is $z + z_0 = xx_0 + yy_0$.

30. Determine the tangent plane and normal line to the hyperboloid $x^2 - 4y^2 + 9z^2 = 36$ at the point $(2, 1, 2)$.

31. Study the surface $xyz = 1$. Show that the volume included between any tangent plane and the coordinate planes is constant.

32. Study the surface $z = (x^2 + y^2)(x^2 + y^2 - 1)$. Determine the extremes.

33. At what angle does a line through the origin and equally inclined to the positive axes cut the surface $2z = x^2 + y^2$?

34. Determine the tangent line and the normal plane at the point $(1, 3/8, 5/8)$ on the curve of intersection of the surfaces $x + y + z = 2$ and $x^2 + 4y^2 - 4z^2 = 0$.

35. Determine the tangent line and the normal plane to the curve $x = 2\cos t$, $y = 2\sin t$, $z = t^2$ at $t = \pi/2$ and at $t = \pi$.

36. Find the length of one turn of the conical spiral $x = t\cos(a\log t)$, $y = t\sin(a\log t)$, $z = bt$, starting from $t = t$.

37. Determine the length of the curve $x = a\cos\theta\cos\phi$, $y = a\cos\theta\sin\phi$, $z = a\sin\phi$, from $\phi = \phi_1$ to $\phi = \phi_2$, where θ is given in terms of ϕ by the equation $\theta = k\log\operatorname{ctn}(\pi/4 - \phi/2)$. (Loxodrome on the sphere.)

38.*† Show that the surfaces $f(x, y, z) = 0$ and $\phi(x, y, z) = 0$ cut each other at right angles if $f_x\phi_x + f_y\phi_y + f_z\phi_z = 0$.

39.* Show that the surfaces

$$x^2/(a^2+\lambda) + y^2/(b^2+\lambda) + z^2/(c^2+\lambda) = 1, \qquad a > b > c > 0,$$

are always (*i*) ellipsoids if $\lambda > -c^2$, (*ii*) hyperboloids of one sheet if $-b^2 < \lambda < -c^2$, (*iii*) hyperboloids of two sheets if $-a^2 < \lambda < -b^2$.

(Confocal Quadrics.)

Show also that these surfaces cut each other mutually at right angles.

If $x = r\cos\theta\cos\phi$, $y = r\cos\theta\sin\phi$, $z = r\sin\theta$ (polar coordinates), find $\partial u/\partial r$, $\partial u/\partial\theta$, and $\partial u/\partial\phi$ for each of the following functions:

40. $u = x^2 + y^2 + z^2$. **41.** $u = x^2 + y^2 - z^2$. **42.** $u = ze^{x+y}$.

43. Compute $\partial u/\partial x$, $\partial u/\partial y$, and $\partial u/\partial z$ if $u = r^2(\sin^2\theta + \sin^2\phi)$, where r, θ, ϕ are defined as in Exs. 40–42.

44.† Show that the centroid $(\bar{x}, \bar{y})$ of a plane area in polar coordinates (ρ, θ) is

$$\bar{x} = \frac{\int\int \rho^2 \cos\theta \, d\rho \, d\theta}{\int\int \rho \, d\rho \, d\theta}, \quad \bar{y} = \frac{\int\int \rho^2 \sin\theta \, d\rho \, d\theta}{\int\int \rho \, d\rho \, d\theta},$$

where the integrals are extended over the given area.

CHAPTER XIX

DIFFERENTIAL EQUATIONS

PART I. ORDINARY DIFFERENTIAL EQUATIONS OF THE FIRST ORDER

173. Definitions. An equation involving derivatives or differentials is called a *differential equation*. An ***ordinary*** differential equation is one involving only total derivatives. A ***partial*** differential equation is one involving partial derivatives.

The ***order*** of a differential equation is the order of the highest derivative present in it.

The ***degree*** of a differential equation is the exponent of the highest power of the highest derivative, the equation having been made rational and integral in the derivatives which occur in it.

EXAMPLES.

(1) $\dfrac{dg}{dt} = kt$ (First order, first degree.)

(2) $\dfrac{ds}{dt} + \dfrac{d^2s}{dt^2} = ks$ (Second order, first degree.)

(3) $\left[1 + \left(\dfrac{dy}{dx}\right)^2\right]^3 = a\left(\dfrac{d^2y}{dx^2}\right)^2$ (Second order, second degree.)

(4) $\dfrac{\partial^2 u}{\partial x^2} + \dfrac{\partial^2 u}{\partial y^2} = 1$ (Second order, first degree.)

Such equations constantly arise in the applications of mathematics to the physical sciences. Many simple examples have already been treated in the text.

174. Elimination of Constants. Differential equations also arise in the elimination of arbitrary constants from an equation.

EXAMPLE 1. Thus, if A and B are arbitrary constants, then equation $y = Ax + B$ represents a straight line in the plane, and by a proper choice of A and B represents any line one pleases in the plane except a vertical line. One differentiation gives $m = dy/dx = A$, which represents all lines of slope A. A second differentiation gives

$$\text{(1)} \qquad \textit{flexion} = b = d^2y/dx^2 = 0,$$

which represents all non-vertical lines in the plane, since all these and on other curves have a flexion identically zero.

EXAMPLE 2. Any circle whose radius is a given constant r is represented by the equation

$$\text{(2)} \qquad (x - A)^2 + (y - B)^2 = r^2,$$

from which A and B may be eliminated as in the preceding example. Differentiating once,

$$\text{(3)} \qquad x - A + (y - B)y' = 0,$$

where $y' = dy/dx$. Differentiating again,

$$\text{(4)} \qquad 1 + y'^2 + (y - B)y'' = 0,$$

where $y'' = d^2y/dx^2$. Solving (3) and (4) for $x - A$ and $y - B$ and substituting these values into (2), so as to eliminate A and B, we find

$$\text{(5)} \qquad (1 + y'^2)^3 = r^2y''^2.$$

This says that every one of these circles, regardless of the position of its center, has the curvature $1/r$, — a statement which absolutely characterizes these circles.

In general, if

$$\text{(6)} \qquad f(x, y, c_1, c_2, \cdots, c_n) = 0$$

is an equation involving x, y, and n independent arbitrary constants $c_1, c_2, \cdots, c_n$, n differentiations in succession with regard to x give

$$\text{(7)} \qquad \frac{df}{dx} = 0, \quad \frac{d^2f}{dx^2} = 0, \quad \cdots, \quad \frac{d^nf}{dx^n} = 0;$$

these equations, together with (6), form a system of $n + 1$

equations from which the constants $c_1, c_2, \cdots, c_n$ may be eliminated. The result is a differential equation of the nth order free from arbitrary constants, and of the form

(8) $$\phi(x, y, y', y'', \cdots, y^{(n)}) = 0.$$

Equation (6) is called the ***primitive*** or the ***general solution*** of (8). The term *general solution* is used because it can be shown that all possible solutions of an ordinary differential equation of the nth order can be produced from any solution that involves n independent arbitrary constants, with the exception of certain so-called "singular solutions" not derivable from the one general solution (6).

Thus, to solve an ordinary differential equation of the *nth* order is understood to mean to find a relation between the variables and n arbitrary constants. These latter are called the *constants of integration.*

If, in the general solution, particular values are assigned to the constants of integration, a *particular solution* of the differential equation is obtained.

175. Integral Curves. An ordinary differential equation of the first order,

(1) $$\phi(x, y, y') = 0, \text{ or } y' = f(x, y),$$

where $y' = dy/dx$, has a general solution involving *one* arbitrary constant c:

(2) $$F(x, y, c) = 0.$$

This represents a singly infinite *set* or *family* of curves, there being in general one curve for each value of c. Any curve of the family can be singled out by assigning to c the proper value.

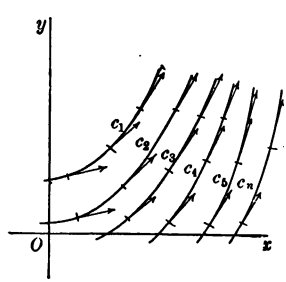

FIG. 86.

The differential equation determines these curves by assigning, for each pair of values of x and y, that is, at each point of the plane, a value of the slope y' $[=f(x, y)]$ of the particular curve going through that point. Thus the curves are outlined by the directions of their tangents in much the way that iron filings sprinkled over a glass plate arrange themselves in what seem to the eye to be curves when a magnet is placed beneath the glass. Straws on water in motion create the same optical illusion.

A differential equation of the second order:

$$\phi(x, y, y', y'')=0, \text{ or } y'' = f(x, y, y'),$$

has a general solution involving two arbitrary constants,

$$F(x, y, c_1, c_2) = 0.$$

This represents a *doubly infinite* or *two-parameter family* of curves; for each constant, independently of the other, can have any value whatever. The extension of these concepts to equations of higher order is obvious.

The curves which constitute the solutions are called the ***integral curves*** of the differential equation.

EXERCISES

Find the differential equations whose general solutions are the following, the c's denoting arbitrary constants:

1. $x^2 + y^2 = c^2$. *Ans.* $x + yy' = 0$.

2. $x^2 - y^2 = cx$. *Ans.* $x^2 + y^2 = 2xyy'$.

3. $y = ce^x - \frac{1}{2}(\sin x + \cos x)$. *Ans.* $y' = y + \sin x$.

4. $y = cx + c^2$. *Ans.* $y = y'x + y'^2$.

5. $y = cx + f(c)$. *Ans.* $y = y'x + f(y')$.

6. $y = c_1e^{2x} + c_2e^{3x}$. *Ans.* $y'' - 5y' + 6y = 0$.

7. $y = c_1e^{ax} + c_2e^{bx}$ *Ans.* $y'' - (a+b)y' + aby = 0$.

8. $xy = c + c^2x$. *Ans.* $x^4y'^2 = y'x + y$.

9. $y = (c_1 + x)e^{3x} + c_2e^x$. *Ans.* $y'' - 4y' + 3y = 2e^{3x}$.

10. $y = c_1e^x + c_2e^{2x} + c_3e^{3x}$. *Ans.* $y''' - 6y'' + 11y' - 6y = 0$.

11. $r = c \sin \theta$. *Ans.* $r \cos \theta = r' \sin \theta$.

12. $r = e^{c\theta}$. *Ans.* $r \log r = r'\theta$.

13. Assuming the differential equation found in Ex. 1, indicate the values of $y'(= -x/y)$ at a large number of points (x, y) by short straight-line segments through each point in the correct direction. Continue doing this at points distributed over the plane until a set of curves is outlined. Are these curves given in Ex. 1?

14. Proceed as in Ex. 13 for the equation $y' = y/x$. Do you recognize the set of curves? Can you *prove* that your guess is correct?

15. Draw a figure to illustrate the meaning of $y' = x^2$. Find y. Generalize the problem to the case $y' = f(x)$.

16. Find that curve of the set given in Ex. 1 which passes through (1, 2). Find its slope (value of y') at that point. Do these three values of (x, y, y') satisfy the differential equation given as the answer in No. 1?

17. Proceed as in Ex. 16 for the equation of Ex. 2.

18. Proceed as in Ex. 16 for the first equation of Ex. 15.

19. Find the differential equation of all circles having their centers at the origin.

20. Find the differential equation of all parabolas with given latus rectum and axes coincident with the x-axis.

21. Find the differential equation of all parabolas with axes falling in the x-axis.

22. Find the differential equation of a system of confocal ellipses.

23. Find the differential equation of a system of confocal hyperbolas.

24. Find the differential equation of the curves in which the subtangent equals the abscissa of the point of contact of the tangent.

25. A point is moving at each instant in a direction whose slope equals the abscissa of the point. Find the differential equation of all the possible paths.

26. Write the differential equation of linear motion with constant acceleration; of linear motion whose acceleration varies as the square of the displacement. The same for angular motion of rotation.

27. A bullet is fired from a gun. Write the differential equations which govern its motion, air resistance being neglected. How must these equations be modified, if air resistance is assumed proportional to velocity?

176. General Statement. We shall now consider methods for solving differential equations. Since the most common properties of *curves* involve slope and curvature, and since in the theory of *motion* we deal constantly with speed and acceleration, *the differential equations of the first and second orders are of prime importance.*

Ordinary differential equations of the first order and first degree have the form

$$(1) \qquad M + N\frac{dy}{dx} = 0, \text{ or } M\,dx + N\,dy = 0,$$

where M and N are functions of x and y.

No general method is known for solving all such differential equations in terms of elementary functions. We proceed to give some standard methods of solution in special cases.

177. Type I. Separation of Variables. It may happen that M involves x only, and N involves y only. The variables are then said to be *separated* and the primitive is found by direct integration:

$$\int M\,dx + \int N\,dy = C,$$

C being an arbitrary constant.

EXAMPLE 1. A particle is falling through air such that the resistance is proportional to the speed. If the particle starts from rest, what is its speed at any time?

Since acceleration is dv/dt, and since this is equal to g diminished by a term proportional to v, we have

$$\frac{dv}{dt} = g - av.$$

Separating variables:

$$\frac{dv}{g - av} = dt.$$

Integrating:

$$-\frac{1}{a}\log(g - av) = t + k,$$

or

$$g - av = e^{-a(t+k)}.$$

Since the particle starts from rest we have $v = 0$ when $t = 0$. Substituting these values in the last equation we have $g = e^{-ak}$;

hence $$g - av = e^{-at-ak} = ge^{-a_t},$$

or $$v = (g/a)(1 - e^{-at}).$$

Example 2. Given $(x^2 + 1)(y + 1)\ dy + xy^2\,dx = 0$. Determine the relation between x and y.

Separating: $$\frac{y+1}{y^2}\,dy + \frac{x}{x^2+1}\,dx = 0.$$

Integrating: $\log y - 1/y + \log\sqrt{x^2+1} = k.$

Let $k = -\log c$, rearrange and combine terms; the result is

$$\log(c\,y\sqrt{x^2+1}) = 1/y$$

or $$c\,y\sqrt{x^2+1} = e^{1/y}.$$

178. Type II. Homogeneous Equations. When M and N are homogeneous * in x and y and of the same degree, the equation is said to be *homogeneous*. If we write the equation in the form

$$\frac{dy}{dx} = -\frac{M}{N},$$

and make the substitution

$$y = vx, \quad \frac{dy}{dx} = v + \frac{x\,dv}{dx},$$

we obtain a new equation in which the variables can be separated.

Example 1.

(1) $$(xy + y^2)\,dx + (xy - x^2)\,dy = 0,$$

or

(2) $$\frac{dy}{dx} = \frac{xy + y^2}{x^2 - xy}.$$

Substituting as above:

* Polynomials are homogeneous in x and y when each term is of the same degree. In general, $f(x, y)$ is homogeneous if $f(kx, ky) = k^n f(x, y)$ for some one value of n and for all values of k.

(3) $$v + x\frac{dv}{dx} = \frac{vx^2 + v^2x^2}{x^2 - vx^2} = \frac{v + v^2}{1 - v},$$

or $$x\frac{dv}{dx} = \frac{2v^2}{1 - v};$$

separating variables, $$\frac{1 - v}{2v^2}dv = \frac{dx}{x}.$$

Integrating: $$-\frac{1}{2v} - \frac{1}{2}\log v = \log x + c.$$

Replacing v by y/x,

$$-\frac{x}{2y} - \frac{1}{2}\log\frac{y}{x} = \log x + c,$$

or $$\log xy = -\frac{x}{y} - 2c;$$

hence

(4) $$xy = e^{-x/y-2c},$$

or $$xy = ke^{-x/y},$$

where $$k = e^{-2c}.$$

CHECK: Differentiating both sides of (4) with respect to x, we find

(5) $$y\,dx + x\,dy = ke^{-x/y}\left[-\frac{y\,dx - x\,dy}{y^2}\right];$$

dividing the two sides of (5) by the corresponding sides of (4) respectively

(6) $$[y\,dx + x\,dy] \div xy = -\frac{y\,dx - x\,dy}{y^2};$$

show that (6) agrees with (1).

EXERCISES

Solve the following exercises by separating the variables:

1. $x\,dy + y\,dx = 0.$ *Ans.* $xy = c.$
2. $x\sqrt{1 + y^2}\,dx - y\sqrt{1 + x^2}\,dy = 0.$ *Ans.* $\sqrt{1 + x^2} = \sqrt{1 + y^2} + c.$
3. $\sin\theta\,dr + r\cos\theta\,d\theta = 0.$ *Ans.* $r\sin\theta = c.$
4. $x\sqrt{1 + y}\,dx = y\sqrt{1 + x}\,dy.$

Solve the following homogeneous equations

5. $(x + y)\,dx + (x - y)\,dy = 0.$ *Ans.* $x^2 + 2xy - y^2 = c.$
6. $(x^2 + y^2)\,dx = 2xy\,dy.$ *Ans.* $x^2 - y^2 = cx.$
7. $(3x^2 - y^2)\,dy = 2xy\,dx.$ *Ans.* $x^2 - y^2 = cy^3.$
8. $(x^2 + 2xy - y^2)\,dx = (x^2 - 2xy - y^2)\,dy.$
   Ans. $x^2 + y^2 = c(x + y).$

The following Exs. 9–18 are intended partially for practice in recognizing types:

9. $\sqrt{1-y^2}\,dx + \sqrt{1-x^2}\,dy = 0.$ *Ans.* $\sin^{-1} x + \sin^{-1} y = c.$

10. $x^3\,dx + (3\,x^2y + 2\,y^3)\,dy = 0.$ *Ans.* $x^2 + 2\,y^2 = c\sqrt{x^2+y^2}.$

11. $dy + y\sin x\,dx = \sin x\,dx.$

12. $r\,d\theta = \tan\theta\,dr.$

13. $(y-1)\,dx = (x+1)\,dy.$

14. $y\,dx + (x-y)\,dy = 0.$

15. $x(1+y^2)\,dx = y\,(1+x^2)\,dy.$

16. $(9\,x^2+y^2)\,dx = 2\,xy\,dy.$

17. $\dfrac{dy}{dx} \div x = c.$

18. $\dfrac{dy}{dx} \div y = x.$

19. In Ex. 1 above, draw a figure to represent the direction of the integral curves at various points. Hence solve the equation geometrically.

20. A point moves so that the angle between the x-axis and the direction of the motion is always double the vectorial angle. Determine the possible paths. *Ans.* $\dfrac{xy}{x^2+y^2} = cx;\ c > 0.$

21. Proceed as in Ex. 20 for a point moving so that its radius vector always makes equal angles with the direction of the motion and the x-axis. *Ans.* $r = c\sin\theta.$

22. The speed of a moving point varies jointly as the displacement and the sine of the time. Determine the displacement in terms of the time. *Ans.* $s = ce^{-k\cos t}.$

23. Find the value of y if its logarithmic derivative with respect to x is x^2.

24. Determine the curve whose subnormal is constant and which passes through the point (2, 5).

25. Determine the curve whose subtangent at any point (x, y) is $(1+x)$, and which passes through (0, 3).

26. Determine the curve passing through (5, 4) such that the length of the normal at any point (§ 30) equals the distance of the point from the origin.

27. When a wheel is driven by a belt the tension at P and the angle θ are connected by the equation $dT/d\theta = kT$, k being a known constant.

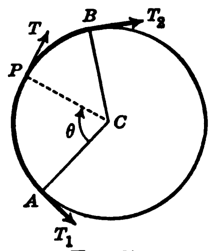

FIG. 87.

If $T_1 = 200$ lb., $k = 0.1$, and $ACB = 60°$, what is T_2?

If $T_1 = 500$ lb., $T_2 = 550$ lb., and $ACB = 90°$, what is k?

28. In a chemical reaction A is the quantity of active matter originally present, q the quantity of product at time t; these are related through the equation $dq/dt = k(A - q)$.

Express q as a function of it.

29. In a bimolecular chemical reaction the original amounts of active substances are A and B; the product q formed in time t is to be determined from the equation

$$dq/dt = k(A - q)(B - q).$$

Express q in terms of t. Consider the special case $A = B$

30. The differential equation of the adiabatic expansion of a gas is $kp\,dv + v\,dp = 0$. Show that $p = cv^{-k}$. Find c if $k = .001$, and $v = 100$ when $p = 10$.

31. The rectilinear motion of a particle under the action of a central force which varies as the inverse square of the distance from a fixed point is $v\,dv/dt = k^2/t^2$, where v is the speed and t the time. Express v in terms of t.

32. Solve Helmholtz's equation for the strength of an electric current, $C = E/R - (L/R)(dC/dt)$, E, L and R being constants. If $C = 0$ when $t = 0$, show that $C = (E/R)(1 - e^{-Rt/L})$.

179. Type III. Linear Equations. This name is applied to equations of the form

$$(1) \qquad \frac{dy}{dx} + Py = Q,$$

where P and Q do not involve y, but may contain x. Its solution can be obtained by first finding a particular solution of the ***reduced equation,***

$$\frac{d\bar{y}}{dx} + P\bar{y} = 0, \tag{1'}$$

where $\bar{y}$ is a new quantity introduced for convenience in what follows; and where Q is replaced by zero. In (1′) the variables can be separated (see § 179), and we get

$$\bar{y} = e^{-\int P\,dx}$$

as a *particular* solution, the constant C of integration being given the particular value 0.

If we make the substitution

$$y = v \cdot \bar{y}, \tag{2}$$

where v is a function of x to be determined, the equation (1) becomes

$$v\frac{d\bar{y}}{dx} + \bar{y}\frac{dv}{dx} + P\,v\bar{y} = Q,$$

or

$$v\left(\frac{d\bar{y}}{dx} + P\bar{y}\right) + \bar{y}\frac{dv}{dx} = Q.$$

The first term vanishes by (1′) leaving

$$\bar{y}\frac{dv}{dx} = Q, \text{ or } dv = \frac{Q}{\bar{y}}dx = [Qe^{\int P\,dx}]\,dx.$$

Hence

$$v = \int\frac{Q}{\bar{y}}dx + c = \int[Qe^{\int P\,dx}]\,dx + c$$

and

$$y = v\bar{y} = e^{-\int P\,dx}\left\{\int[Qe^{\int P\,dx}]\,dx + c\right\}. \tag{3}$$

This equation expresses the solution of any linear equation. It should not be used as a formula; rather, the substitution (2) should be made in each example.

EXAMPLE. Given

(1) $$\frac{dy}{dx} + 3x^2y = x^5,$$

the reduced equation in the new letter $\bar{y} = y/v$ is

(1′) $$\frac{d\bar{y}}{dx} + 3x^2\bar{y} = 0, \quad \text{whence} \quad \bar{y} = e^{-x^3}.$$

Hence the substitution $y = v \cdot \bar{y}$ becomes

(2) $$y = v\,e^{-x^3}, \quad \text{whence} \quad \frac{dy}{dx} = e^{-x^3}\frac{dv}{dx} - 3\,vx^2e^{-x^3},$$

and (1) takes the form

$$\left[e^{-x^3}\frac{dv}{dx} - 3\,vx^2e^{-x^3}\right] + 3\,x^2\,[ve^{-x^3}] = x^5.$$

This reduces, as we foresaw in general above, to the form

$$e^{-x^3}\frac{dv}{dx} = x^5, \quad \text{or} \quad \frac{dv}{dx} = x^5\,e^{x^3},$$

whence $$v = \int x^5\,e^{x^3}\,dx + c = \tfrac{1}{3}\,[x^3\,e^{x^3} - e^{x^3}] + c,$$

or, returning by (2) to y:

(3) $$y = v\,e^{-x^3} = \tfrac{1}{3}\,[x^3 - 1] + ce^{-x^3}.$$

CHECK. Differentiating both sides,

(4) $$\frac{dy}{dx} = x^2 - 3\,x^2\,ce^{-x^3};$$

eliminating c by multiplying (3) by $3\,x^2$ and adding to (4),

$$\frac{dy}{dx} + 3\,x^2y = x^5.$$

The result (3) may also be obtained by direct substitution from (1). Sufficient practice in the direct solution, as in the preceding example, is strongly advised.

180. Equations Reducible to Linear Equations. Certain forms of equations may be reduced to linear equations by a proper change of variable. No general rule can be given, and the proper substitution is usually to be formed by trial.

EXAMPLE. $$\sec^2 y\,\frac{dy}{dx} + 3\,x^2\tan y = x^5.$$

Letting $\tan y = z$, we have

$$\frac{dz}{dx} + 3\,x^2z = x^5,$$

which is linear in z and has the same form as the example solved in § 179.

The equation

$$\frac{dy}{dx} + Py = Qy^n, \qquad (n \text{ a constant.})$$

called the extended linear equation is always reducible to the linear type by putting $y^{1-n} = z$.

EXAMPLE. Given

$$\frac{dy}{dx} + \frac{y}{x} = xy^3. \quad \text{Put } z = y^{-2}.$$

Then $$\frac{dz}{dx} = -2y^{-3}\frac{dy}{dx}, \quad \text{or} \quad \frac{dy}{dx} = -(1/2)\,y^3\frac{dz}{dx}.$$

Thus $$-(1/2)\,y^3\frac{dz}{dx} + \frac{y}{x} = xy^3$$

and $$\frac{dz}{dx} - 2\frac{z}{x} = -2x.$$

Here $$P = -\frac{2}{x}, \quad \int P\,dx = -2\log x, \quad e^{\int P\,dx} = x^{-2};$$

so that $$z = x^2\left(\int -\frac{2}{x}dx + c\right) = -2x^2\log x + cx^2 = y^{-2},$$

and finally $x^2y^2(c - 2\log x) = 1$. Check this result.

EXERCISES

Solve the following equations and check each answer.

1. $\dfrac{dy}{dx} - xy = e^{x^2}/2.$

2. $\dfrac{dy}{dx} + 3x^2y = 3x^5.$

3. $\dfrac{dy}{dx} + y\cos x = \sin 2x.$

4. $x\dfrac{dy}{dx} + y = \log x.$

5. $\dfrac{dy}{dx} + \dfrac{y}{x} = y^3.$

6. $\dfrac{dy}{dx} + y = xy^3.$

7. $\dfrac{dr}{d\theta} - 2r\theta = r^2\theta^3.$

8. $xy^2\dfrac{dy}{dx} - y^3 = x^2.$

9. $\cos^2 x\dfrac{dy}{dx} + y = \tan x.$

10. $r\dfrac{dr}{d\theta} = (1 + r^2)\sin\theta.$

11. $\dfrac{ds}{dt} = -s + t.$

12. $\dfrac{dy}{dx} + y = e^{-x}.$

13. $dy - y\,dx = \sin x\,dx.$

14. $\sec\theta\,dr + (r - 1)\,d\theta = 0.$

15. $(x^2 + 1)\,dy = (xy + k)\,dx$. **16.** $x\,dy + y\,dx = xy^2 \log x\,dx$.

17. The equation of a variable electric current is

$$L\frac{di}{dt} + Ri = e,$$

where L and R are constants of the circuit, i is the current, and e the electromotive force of the circuit. Calculate i in terms of t, 1°, if e is constant; 2°, if $e = e_0 \sin \omega t$.

Ans. 2° $i = \dfrac{e_0}{\sqrt{R^2 + \omega^2 L^2}} \sin(\omega t - \phi) + ce^{-Rt/L}$, $\phi = \arctan(\omega L/R)$.

181. Other Methods. Non-linear Equations. A variety of other methods are given in treatises on Differential Equations; some of these are indicated among the exercises which follow. Noteworthy among these are the possibility of making advantageous *substitutions;* and — what amounts to a special type of substitution — the possibility of writing the given equation in the form of a *total differential*, $dz = 0$, where z is a known function of x and y which leads to the general solution z = constant (see Exs. 5–12, below).

Equations not linear in y' may often be solved. If the given equation can be solved for y', several values of y' may be found, each of which constitutes a differential equation: the general solution of the given equation means the totality of all of the solutions of all of these new equations.

EXERCISES

Solve the following equations, using the indicated substitutions:

1. $y^2\,dy + (y^3 + x)\,dx = 0$. (Put $v = y^3$.)

2. $s\,dt - t\,ds = 2\,s\,(t - s)\,dt$. (Put $s = tv$.)

3. $x\,dy - y\,dx = (x^2 - y^2)\,dy$. (Put $y = vx$.)

4. $u^2 v^2 (u\,dv + v\,du) = (v + v^2)\,dv$. (Put $uv = x$, $v = y$.)

5. Solve the equation $(3\,x^2 + y)\,dx + (x + 3\,y^2)\,dy = 0$.

[Hint. If we put $z = x^3 + xy + y^3$, this equation reduces to $dz = 0$; for $dz = (\partial z/\partial x)\,dx + (\partial z/\partial y)\,dy$. But $dz = 0$ gives z = const., hence

$x^3 + xy + y^3 = c$ is the general solution. Such an equation as that given in this example is called an ***exact differential equation.***]

6. Solve the equation $x\,dy - y\,dx = 0$.

[HINT. This equation can be solved by previous methods; but it is easier to divide both sides by x^2 and notice that the resulting equation is $d\,(y/x) = 0$; hence the general solution is $y/x = c$. A factor which renders an equation exact ($1/x^2$ in this example) is called an ***integrating factor.***]

7. Solve the equation $(x^2 + 2\,xy^2)\,dx + (2\,x^2\,y + y^2)\,dy = 0$.

[HINT. Put $z = x^3/3 + x^2y^2 + y^3/3$.]

8. Solve the equation $(s + t \sin s)\,ds + (t - \cos s)\,dt = 0$.

[HINT. Arrange: $s\,ds + [t \sin s\,ds - \cos s\,dt] + t\,dt = 0$; integrate this, knowing that the bracketed term is $-d\,(t \cos s)$.]

9. Solve the equation $x\,dy - (y - x)\,dx = 0$.

[HINT. Arrange: $[x\,dy - y\,dx] + x\,dx = 0$; divide by x^2, and compare Ex. 6.]

10. Show that $[f\,(x) + 2\,xy^2]\,dx + [2\,x^2y + \phi\,(y)]\,dy = 0$ can always be solved by analogy to Ex. 7.

11. Show that $[f\,(x) + y]\,dx - x\,dy$ can always be solved by analogy to Ex. 9. Solve $(x^2 + y)\,dx - x\,dy = 0$. *Ans.* $x - y/x = c$.

12. Solve the equation $(r - \tan\theta)\,d\theta + (r \sec\theta + \tan\theta)\,dr = 0$.

[HINT. Multiply both sides by the *integrating factor* $\cos\theta$; $-\sin\theta\,d\theta + r\,dr + d\,(r \sin\theta) = 0$; integrate term by term.]

13. When a family of curves crosses those of another family everywhere at right angles, the curves of either family are called the ***orthogonal trajectories*** of those of the other family.

Find the orthogonal trajectories of the family of circles

$$x^2 + y^2 = r^2.$$

[HINT. If the differential equation of the first family be $dy/dx = f\,(x, y)$, then the differential equation of the orthogonal trajectories is $dx/dy = -f\,(x, y)$, for any point of intersection (x, y) the slope of the curve of one system is the negative reciprocal of the slope of the curve of the other.

In this example the differential equation of the given family is $x\,dx + y\,dy = 0$. It is evident that the differential equation of the orthogonal

family is obtained by replacing dy and dx by $-dx$ and dy, respectively; hence the desired equation is $x\,dy - y\,dx = 0$, whence the curves are $y = cx$, *i.e.* the family of all straight lines through the origin.]

14. Find the orthogonal trajectories of the exponential curves.

$$y = e^x + k.$$

[HINT. The differential equation is $dy/dx = e^x$. The orthogonal family is defined by the equation $dy/dx = -e^{-x}$, whence the trajectories are $y = e^{-x} + c$. Draw the figure.]

Determine the orthogonal trajectories of the following families, and draw diagrams in illustration of each:

15. $x + y = k$.

16. $xy = k$.

17. $y^2 = 4k(x + k)$.

18. $x^2 + y^2 = 2 \log x + c$.

19. $2x^2 + y^2 = c^2$.

20. $x^2 + y^2 = kx$.

PART II. ORDINARY DIFFERENTIAL EQUATIONS OF THE SECOND ORDER

182. Special Types. We first consider some very special forms of equations of the second order that are most frequently used in the application of mathematics to physics, namely:

[I] $$\frac{d^2y}{dx^2} = \pm k^2 y \quad [k = \text{constant.}]$$

[II] $$A\frac{d^2y}{dx^2} + B\frac{dy}{dx} + Cy = 0 \quad [A, B, C, \text{ constants.}]$$

[III] $$A\frac{d^2y}{dx^2} + B\frac{dy}{dx} + Cy = F(x). \quad [A, B, C, \text{ constants.}]$$

These are all special forms of the general equation of the second order $\phi(x, y, dy/dx, d^2y/dx^2) = 0$.

[IV] We shall consider other special forms also, some of which include the above; namely, the cases that arise when one or more of the quantities x, y, dy/dx, are absent from the equation. (See § 186, p. 334.)

183. Type I. This type of equation arises in problems on *motion* in which the tangential acceleration $d^2 s/dt^2$ is proportional to the distance passed over:

$$\frac{d^2 s}{dt^2} = \pm k^2 s, \tag{1}$$

a form which is equivalent to [I], written in the letters s and t. If we multiply both sides of this equation by the speed $v = ds/dt$ and then integrate with respect to t, we obtain

$$\int \frac{ds}{dt}\frac{d^2s}{dt^2}\,dt = \int \pm k^2 s \frac{ds}{dt}\,dt; \tag{2}$$

but we know that

$$\int \frac{ds}{dt}\frac{d^2s}{dt^2}\,dt = \int v\frac{dv}{dt}\,dt = \int v\,dv = \frac{1}{2}v^2 + c = \frac{1}{2}\left(\frac{ds}{dt}\right)^2 + c,$$

and

$$\int \pm k^2 s\frac{ds}{dt}\,dt = \pm k^2 \int s\,ds = \pm \frac{k^2}{2}s^2 + c';$$

hence (2) becomes*

$$\frac{v^2}{2} = \frac{1}{2}\left(\frac{ds}{dt}\right)^2 = \pm\frac{k^2}{2}(s^2 + C_1). \tag{3}$$

Case 1. If the sign before k^2 is +, (3) becomes

$$v = \frac{ds}{dt} = k\sqrt{s^2 + C_1}, \tag{4}$$

whence
$$\int \frac{ds}{\sqrt{s^2+C_1}} = \int k\,dt + C_2,$$

$$\log\left(s + \sqrt{s^2 + C_1}\right) = kt + C_2; \tag{5}$$

or, solving for s,

$$s = Ae^{kt} + Be^{-kt}. \tag{6}$$

* This is often called the *energy integral*, for if we multiply through by the mass m, the expression $mv^2/2$ on the left is precisely the kinetic energy of the body.

where $2A = e^{C_1}$ and $2B = -C_1 e^{-C_1}$ are two new arbitrary constants.

By means of the hyperbolic functions $\sinh u = (e^u - e^{-u})/2$ and $\cosh u\,(e^u + e^{-u})/2$ this result may also be written in the form

$$(7) \qquad s = a \sinh (kt) + b \cosh (kt),$$

where $\qquad b + a = 2A$ and $b - a = 2B$.

Case 2. **If the sign before k^2 is $-$**, C_1 must be negative also, or else v is imaginary; hence we set $C_1 = -a^2$ and write

$$(4_2) \qquad v = \frac{ds}{dt} = k\sqrt{a^2 - s^2},$$

or

$$\int \frac{ds}{\sqrt{a^2 - s^2}} = \int k\,dt + C_2,$$

whence

$$(5_2) \qquad \sin^{-1}\left(\frac{s}{a}\right) = kt + C_2;$$

or solving for s:

$$(6_2) \qquad s = a \sin (kt + C_2) = A \sin kt + B \cos kt,$$

where $A = a \cos C_2$ and $B = a \sin C_2$ are two new arbitrary constants.

Equation (6_2) is the characteristic equation of ***simple harmonic motion***; the amplitude of the motion is a, the period is $2\pi/k$, and the phase is $-C_2/k$.

The differential equation (1) was first found in § 88, p. 155. We now see that the general simple harmonic motion (6_2) is the only possible motion in which the tangential acceleration is a negative constant times the distance from a fixed point; *i.e.* it is the only possible type of ***natural vibration*** under the assumptions of § 76, p. 125.

EXERCISES

Solve each of the following equations:

1. $\dfrac{d^2s}{dt^2} = s.$

2. $\dfrac{d^2s}{dt^2} = 4\,s.$

3. $\dfrac{d^2s}{dt^2} = -\,s.$

4. $\dfrac{d^2s}{dt^2} = -\,9\,s.$

5. Find the curves for which the flexion (d^2y/dx^2) is proportional to the ordinate (y).

6. Determine the motion described by the equation of Ex. 1 if the speed $v\ (= ds/dt)$ and the distance traversed s are both zero when $t = 0$.

7. Proceed as in Ex. 6 for Ex. 3, and explain your result.

8. Write the solution of Ex. 1 in terms of $\sinh t$ and $\cosh t$. Determine the arbitrary constants by the conditions of Ex. 6, and show that the final answer agrees precisely with that of Ex. 6.

9. Determine the motion described by the equation of Ex. 3 if $v = 2$ and $s = 10$ when $t = 0$; if $v = 0$ and $s = 5$ when $t = 0$.

184. Type II. Homogeneous Linear Equations of the Second Order with Constant Coefficients. The form of this equation is

$$A\frac{d^2y}{dx^2} + B\frac{dy}{dx} + Cy = 0, \tag{1}$$

where A, B, C are constants.

The type just considered is a special case of this one. Following the indications of the results we obtained in § 183, it is natural to ask whether there are solutions of any one of the types we found in the special case.

Trial of e^{kx}. If we substitute $y = e^{kx}$ in (1) we obtain the equation:

$$[Ak^2 + Bk + C]\,e^{kx} = 0. \tag{2}$$

The factor e^{kx} is never zero; *hence k must satisfy the quadratic equation*

$$Ak^2 + Bk + C = 0, \tag{1*}$$

which is called the ***auxiliary equation*** to (1). If the roots of (1*) are *real and distinct, i.e.* if

(3) $$D \equiv B^2 - 4AC > 0,$$

then *these roots k_1 and k_2 are possible values for k*, and the general solution of (1) is

(4) $$y = C_1 e^{k_1 x} + C_2 e^{k_2 x},$$

since a trial is sufficient to convince one that the sum of two solutions of (1) is also a solution of (1); and that a constant times a solution is also a solution.

Trial of $y = e^{\kappa x} \cdot v$. If (3) is not satisfied, the substitution

(5) $$y = e^{\kappa x} \cdot v$$

changes (1) to the form

(6) $$A \frac{d^2 v}{dx^2} + [2\kappa A + B] \frac{dv}{dx} + [A\kappa^2 + B\kappa + C] v = 0,$$

which becomes quite simple if we determine κ so that the term in dv/dx is zero:

(7) $$2\kappa A + B = 0, \quad \text{whence } \kappa = -B/2A;$$

then (6) takes the form

(8) $$\frac{d^2 v}{dx^2} = \frac{B^2 - 4AC}{4A^2} v = -K^2 v,$$

where $K = \sqrt{4AC - B^2}/(2A) = \sqrt{-D}/2A$ is *real* if

(9) $$D \equiv B^2 - 4AC \leqq 0,$$

which is the case we could not solve before.

If $D < 0$, the solutions of (8) are

(10) $$v = C_1 \sin(Kx) + C_2 \cos(Kx),$$

by (6_2), § 183, p. 328; hence the solutions of (1) are

(11) $$y = e^{\kappa x} \cdot v = e^{\kappa x}[C_1 \sin(Kx) + C_2 \cos(Kx)],$$

where $\kappa = -B/(2A)$ and $K = \sqrt{-D}/(2A)$; these values of

κ and K are most readily found by solving (1 *) for k, *since the solutions of* (1*) *are* $k=(-B\pm\sqrt{D})/(2A)=\kappa\pm K\sqrt{-1}$.

If $D=0$, $K=0$, and the solutions of (8) are

(12) $$v = C_1x + C_2;$$

hence the solutions of (1) are

(13) $$y = e^{\kappa x}\cdot v = e^{\kappa x}[C_1x + C_2],$$

where $\kappa = -B/(2A)$ is the solution of (1 *); since when $D=0$, (1*) has only one root $k = -B/(2A)$.

It follows that *the solutions of* (1) *are surely of one of the three forms* (4), (11), (13), *according as* $D = B^2 - 4AC$ *is* $+$, $-$, *or* 0; that is, *according as the roots of the* ***auxiliary equation*** (1*) *are real and distinct, imaginary, or equal*; in résumé:

$D=B^2-4AC$	Character of Roots of (1*)	Values of Roots of (1*)	Solution of (1)
$+$	Real, unequal	k_1, k_2	(4)
$-$	Imaginary	$\kappa\pm K\sqrt{-1}$	(11)
0	Equal	κ	(13)

We illustrate by some examples put, for convenience of comparison, in tabular form.

Examples	1	2	3
Equation (1)	$3y''-4y'+y=0$	$3y''-4y'+\frac{4}{3}y=0$	$3y''-4y'+2y=0$
Auxiliary equation (1*)	$3k^2-4k+1=0$	$3k^2-4k+\frac{4}{3}=0$	$3k^2-4k+2=0$
Roots of (1*)	1, 1/3	2/3, 2/3	$\frac{1}{3}(2\pm\sqrt{-2})$
Solution of (1)	$y=c_1e^x+c_2e^{x/3}$	$y=e^{2x/3}(c_1+c_2x)$	$y=e^{2x/3}\left(c_1\cos\frac{\sqrt{2}}{3}x+c_2\sin\frac{\sqrt{2}}{3}x\right)$

EXERCISES

1. $y'' - 4y' + 3y = 0.$
2. $y'' + 3y' + 2y = 0.$
3. $5y'' - 4y' + y = 0.$
4. $9y'' + 12y' + 4y = 0.$
5. $y'' - 2y' + y = 0.$
6. $y'' + y' + y = 0.$
7. $y'' - 2y' + 3y = 0.$
8. $3y'' + 5y' + 2y = 0.$
9. $y'' - 9y' + 14y = 0.$
10. $2y'' - 3y' + y = 0.$
11. $6y'' - 13y' + 6y = 0.$
12. $y'' - 3y' = 0.$
13. $y'' - 4y = 0.$
14. $y'' + 9y = 0.$
15. $y'' + ky' = 0.$
16. $y'' \pm ky = 0.$

17. If a particle is acted on by a force that varies as the distance and by a resistance proportional to its speed, the differential equation of its motion is

$$d^2x/dt^2 + b\,dx/dt + cx = 0,$$

where $c > 0$ if the force attracts, and $c < 0$ if the force repels. Solve the equation in each case.

18. If in Ex. 17, $b = c = 1$, and the particle starts from rest at a distance 1, determine its distance and speed at any time t. Is the motion oscillatory? If so, what is the period? Solve when the initial speed is v_0.

19. If in Ex. 17, $b = 1$ and $c = -1$, discuss the motion as in Ex. 18.

185. Type III. Non-homogeneous Equations. This type is of the form:

$$A\frac{d^2y}{dx^2} + B\frac{dy}{dx} + Cy = F(x), \tag{1}$$

where A, B, C, are constants, and $F(x)$ is a function of x only. We proceed to show that this form can be solved in a manner exactly analogous to § 179, p. 320. First write down the reduced equation in the new letter v:

$$A\frac{d^2v}{dx^2} + B\frac{dv}{dx} + Cv = 0, \tag{1*}$$

and solve (1^*) by the method of § 184. Let $v = \phi(x)$ be *any one* particular solution of (1^*) (the simpler, the better, except that $v = 0$ is excluded). Then the substitution

$$(2) \qquad y = v \cdot u$$

transforms (1) into

$$(3) \quad (Av'' + Bv' + Cv)\,u + (2\,Av' + Bv)\frac{du}{dx} + Av\frac{d^2u}{dx^2} = F(x);$$

but, since v satisfies (1^*), the first term of (3) is zero; and if we now set $du/dx = w$ temporarily, this equation can be written as the linear equation:

$$(4) \qquad \frac{dw}{dx} + \left\{\frac{2\,Av' + Bv}{Av}\right\} w = \frac{F(x)}{Av},$$

which is precisely of the form solved in § 179. Comparing (4) with (1), § 179, we have

$$(5) \qquad P = \frac{2\,Av' + Bv}{Av}, \quad Q = \frac{F(x)}{Av}.$$

Having found w by § 179, we have

$$u = \int w\,dx + c_2, \quad y = uv = v\left[\int w\,dx + c_2\right],$$

which is the required solution of (1).

EXAMPLE 1. Given the equation

$$(1) \qquad \frac{d^2y}{dx^2} + 3\frac{dy}{dx} + 2\,y = \sin x,$$

we write the reduced equation

$$(1^*) \qquad \frac{d^2v}{dx^2} + 3\frac{dv}{dx} + 2\,v = 0;$$

this is easily solved by the method of § 184; the simplest particular solution is $v = e^{-x}$. Substituting $v = e^{-x}$ in the general work above, we find

$$P = \frac{2\,Av' + Bv}{Av} = 1 \text{ and } Q = \frac{F(x)}{Av} = e^x \sin x;$$

hence $e^{\int P\,dx} = e^x$, and

$$w = e^{-x}\left[\int e^{2x}\sin x\,dx + C_1\right] = \frac{1}{5}e^x(2\sin x - \cos x) + C_1e^{-x},$$

$$u = \int w\,dx + C_2 = \frac{1}{10}e^x(\sin x - 3\cos x) - C_1e^{-x} + C_2,$$

$$y = u\cdot v = \frac{1}{10}(\sin x - 3\cos x) - C_1e^{-2x} + C_2e^{-x}.$$

EXERCISES

1. $y'' - 3y' + 2y = \cos x.$
   Ans. $y = \frac{1}{10}(\cos x - 3\sin x) + c_1e^x + c_2e^{2x}.$

2. $y'' - 4y' + 2y = x.$
   Ans. $y = \frac{1}{2}(x + 2) + c_1e^{(2+\sqrt{2})x} + c_2e^{(2-\sqrt{2})x}.$

3. $y'' + 3y' + 2y = e^x.$ *Ans.* $y = e^x/6 - c_1e^{-2x} + c_2e^{-x}.$

4. $y'' - 2y' + y = x.$ *Ans.* $y = x + 2 + e^x(c_1 + c_2x).$

5. $y'' + y = \sin x.$ *Ans.* $y = -\frac{1}{2}x\cos x + c_1\sin x + c_2\cos x.$

6. $y'' - y' - 2y = \sin x.$
   Ans. $y = \frac{1}{10}(\cos x - 3\sin x) + c_1e^{-x} + c_2e^{2x}.$

7. $y'' + 4y = x^2 + \cos x.$
   Ans. $y = \frac{1}{8}(2x^2 - 1) + \frac{1}{3}\cos x + c_1\cos 2x + c_2\sin 2x.$

8. $y'' - 2y' = e^{2x} + 1.$ *Ans.* $y = \frac{1}{2}x(e^{2x} - 1) + c_1 + c_2e^{2x}.$

9. $y'' - 4y' + 3y = 2e^{3x}.$ *Ans.* $y = xe^{3x} + c_1e^x + c_2e^{3x}.$

10. If a particle moves under the action of a periodic force through a medium resisting as the speed, the equation of motion is

$$d^2s/dt^2 + A\,ds/dt = B\sin Ct.$$

Express s and the speed in terms of t. If $A = B = C = 1$, what is the distance passed over and the speed after 5 seconds, the particle starting from rest?

186. Type IV. One of the quantities x, y, y' absent.

Type IV$_a$: $\phi(y'') = 0$. Solve for y'', to obtain a solution, say $y'' = a$. Then integrate twice. The general solution for each value of y'' is of the form $y = \frac{1}{2}ax^2 + c_1x + c_2$.

In problems of *motion*, this type is equivalent to the statement that $\phi(j_T) = 0$, where $j_T = d^2s/dt^2 = dv/dt$. Hence j_T may have any one of the several *constant* values which satisfy $\phi(j_T) = 0$; but if $j_T = k$, $s = kt^2/2 + c_1t + c_2$ (see Ex. 24, p. 64).

Type IV$_b$: y missing. $\phi(x, y', y'') = 0$. The substitution $m = y' = dy/dx$, $dm/dx = d^2y/dx^2 = y''$, reduces the given equation to an equation of the *first order* in m, x, dm/dx. Solving, if possible, one gets a relation of the form

$$f(m, x, c) = 0.$$

This is again an equation of the first order in x and y, and may be integrated by methods given in Part I, §§ 177–181.

The interpretation in motion problems is particularly vivid and beautiful. Thus $v = ds/dt$ and $j_T = dv/dt = d^2s/dt^2$; hence any equation in j_T, v, t, *with s absent*, is a differential equation of the first order in v. Solving this, we get an equation in v and t; since $v = ds/dt$, this new equation is of the first order in s and t.

Example 1. $$1 + x + x^2\frac{d^2y}{dx^2} = 0.$$

Setting $dy/dx = m$, $$1 + x + x^2\frac{dm}{dx} = 0.$$

Separating variables, $$-dm = \frac{1+x}{x^2}dx.$$

Integrating, $$-m = -\frac{1}{x} + \log x + c_1.$$

Integrating again, $$y = \log x - x\log x + (1 - c_1)x - c_2.$$

Interpret this as a problem in motion, with s and t in place of y and x, and $j_T = dv/dt = d^2s/dt^2$.

Example 2. In a certain motion the space passed over s, the speed v, and the acceleration j_T are connected with the time by the relation $1 + v^2 - j_T = 0$; find s in terms of t.

Placing $j_T = dv/dt$, the equation

$$1 + v^2 - \frac{dv}{dt} = 0$$

is of the first order. The variables can be separated, and the integral is

$$\tan^{-1} v = t + c_1 \text{ or } v = \tan(t + c_1),$$

which is itself a differential equation of the first order if we replace v by ds/dt. Integrating this new equation:

$$\int ds = \int \tan(t + c_1)\, dt + c_2, \text{ or } s = -\log\cos(t + c_1) + c_2.$$

In such a motion problem we usually know the values of v and s for some value of t. If $v = 0$ and $s = 10$ when $t = 0$, for example, c_1 must be zero (or else a multiple of π) and c_2 must be 10; hence

$$s = -\log\cos t + 10.$$

EXAMPLE 3. $$1 + x\frac{dy}{dx} + x^2\frac{d^2y}{dx^2} = 0 = 1 + xm + x^2\frac{dm}{dx}.$$

This can be written $dm/dx + m/x = -1/x^2$,

which is linear in m and x, the solution being

$$m = -\frac{1}{x}\log x + \frac{c_1}{x}.$$

The second integration gives

$$y = -\tfrac{1}{2}[\log x]^2 + c_1 \log x + c_2.$$

Interpret this as a motion problem, and determine c_1 and c_2 to make $y = 10$ and $m = 3$ when $x = 1$.

Type IV$_c$: x missing. $\phi(y, y', y'') = 0$. The substitution $m = y'$ gives

$$y' = m, \quad y'' = \frac{dy'}{dx} = \frac{dy'}{dy}\cdot\frac{dy}{dx} = \frac{dm}{dy}\cdot m;$$

and the transformed equation is an equation of the first order in y and m. We solve this and then restore y' in place of m, whereupon we have left to solve another equation (in x and y) of the first order.

This is precisely the way in which we solved Type I, § 183, Type I being only an *important* special case of Type IV.

EXAMPLE 1. If the acceleration j_T is given in terms of the distance passed over (compare § 188), we have

$$j_T = \frac{d^2s}{dt^2} = \phi(s), \text{ or } \frac{dv}{dt} = \phi(s).$$

This is transformed by the relation

$$j_T = \frac{dv}{dt} = \frac{dv}{ds}\frac{ds}{dt} = \frac{dv}{ds}v,$$

(which is itself *a most valuable formula*) into

$$\frac{dv}{ds}v = \phi(s)$$

in which the variables can be separated; integration gives

$$\frac{1}{2}v^2 = \int \phi(s)\,ds + c,$$

which is called the ***energy integral*** (see footnote, p. 327).

The work cannot be carried further than this without knowing an exact expression for $\phi(s)$. When $\phi(s)$ is given, we proceed as in § 183, replacing v by ds/dt and integrating the new equation:

$$\int \frac{ds}{\sqrt{2\int \phi(s)\,ds + 2c}} = t + k.$$

Unfortunately the indicated integrations are difficult in many cases; often they can be performed by means of a table of integrals. One case in which the integrations are comparatively easy is that already done in § 183.

EXERCISES

1. $y''^2 - 4x^2 = 0$. *Ans.* $y = \pm 1/3\,x^3 + c_1x + c_2$.

2. $y'' = \sqrt{1 + y'^2}$. *Ans.* $2y = c_1e^x + e^{-x}/c_1 + c_2$.

3. $xy'' + y' = x^2$. *Ans.* $y = x^3/9 + c_1 \log x + c_2$.

4. $s\,d^2s/dt^2 + ds/dt = 1$. *Ans.* $s^2 = t^2 + c_1t + c_2$.

5. $\dfrac{d^2s}{dt^2} = \dfrac{1}{\sqrt{s}}$.

6. $\dfrac{d^2y}{dx^2} = \pm k^2y$.

7. $\dfrac{d^2y}{dx^2} = e^{2x}$.

8. $\dfrac{d^2y}{dx^2} = e^{2y}$.

9. $\dfrac{d^2y}{dx^2} = x^2 \cos x$.

10. $\dfrac{d^3y}{dx^3} = x + 3 \sin x$.

11. $\dfrac{d^4y}{dx^4} = e^x - \cos 2x$.

12. $\dfrac{d^2y}{dx^2} = \left[1 + \left(\dfrac{dy}{dx}\right)^2\right]^{3/2}$.

13. Show that Ex. 12 is equivalent to the problem, to find a curve whose radius of curvature is unity.

14. The flexion (d^2y/dx^2) of a beam rigidly embedded at one end, and loaded at the other end, which is unsupported, is $k(l - x)$, where k is a constant and l is the length of the beam. Find y, and determine the constants of integration from the fact that $y = 0$ and $dy/dx = 0$ at the embedded end, where $x = 0$.

15. Find the form of a uniformly loaded beam of length l, embedded at one end only, if the flexion is proportional to $l^2 - 2lx + x^2$, where $x = 0$ at the embedded end.

16. Find the form of a uniformly loaded beam of length l, freely supported at both ends, if the flexion is proportional to $l^2 - 4x^2$ in each half, where x is measured horizontally from the center of the beam.

PART III. GENERALIZATIONS

187. Ordinary Equations of Higher Order. An equation whose order is *greater than two* is called ***an equation of higher order;*** the reason for this is the comparative rarity in applications of equations above the second order. We shall state briefly the generalizations to equations of higher order, however, since they do occur in a few problems, and since it is interesting to know that *pratically the same rules apply in certain types* for higher orders as those we found for order two.

188. Linear Homogeneous Type. The work of § 184 can be generalized to any ***linear homogeneous equation with constant coefficients:***

$$(1) \qquad \frac{d^n y}{dx^n} + a_1 \frac{d^{n-1} y}{dx^{n-1}} + \cdots + a_{n-1} \frac{dy}{dx} + a_n y = 0.$$

Thus if we set $y = e^{kx}$, as in § 184, we find

$$(1^*) \qquad k^n + a_1 k^{n-1} + \cdots + a_{n-1} k + a_n = 0,$$

again called the ***auxiliary*** equation. Corresponding to any real root k_1 there is therefore a solution $e^{k_1 x}$; *if all the roots are real and distinct, the general solution of* (1) *is*

$$(2) \qquad y = C_1 e^{k_1 x} + C_2 e^{k_2 x} + \cdots + C_n e^{k_n x},$$

where $k_1, k_2, \cdots, k_n$ are the roots of (1). Curiously enough, the chief difficulty is not in any operation of the Calculus; rather it is in solving the algebraic equation (1*).

It is easy to show by extensions of the methods of § 184 that *any pair of imaginary roots of* (1*), $k = \kappa \pm K\sqrt{-1}$ *corresponds to a solution of the form*†

(3) $$y = e^{\kappa x}[C' \sin(Kx) + C'' \cos(Kx)],$$

which then takes the place of two of the terms of (2).

Finally, *if a root* $k = \kappa$ *of* (1*) *occurs more than once, i.e.* if the left-hand side of (1*) has a factor $(k - \kappa)^p$, *the corresponding solution obtained as above should be* ***multiplied*** *by the polynomial*

(4) $$B_0 + B_1 x + B_2 x^2 + \cdots + B_{p-1}x^{p-1},$$

where p is the order of multiplicity of the root (*i.e.* the exponent of $(k - \kappa)^p$), and where the B's are arbitrary constants which replace those lost from (2) by the condensation of several terms into one.

The proof is most easily effected by making the substitution $y = e^{\kappa x} \cdot u$, whereupon the transformed differential equation contains no derivative below $d^p u/dx^p$; hence $u =$ the polynomial (4) is a solution of the new equation, and $y = e^{\kappa x}$ times the polynomial (4) is a solution of (1). This work may be carried out by the student in any example below in which (1*) has multiple roots.‡

† This fact is often made plausible by the use of the equations

$$e^{u\sqrt{-1}} = \cos u + \sqrt{-1}\sin u, \quad e^{-u\sqrt{-1}} = \cos u - \sqrt{-1}\sin u;$$

these equations can be derived formally by using the Taylor series for e^v, $\cos u$, $\sin u$, with $v = u\sqrt{-1}$, but they remain only plausible until after a study of the theory of imaginary numbers. The solutions $e^{\kappa \pm K\sqrt{-1}}$ are indicated formally by (2); hence it is plausible that (3) is correct.

A more direct process which avoids any uncertainty concerning imaginaries is almost as easy. For the substitution $y = e^{\kappa x} \cdot u$ (see §184) gives a new equation in u and x which, together with its auxiliary, has coefficients of the form $(d^n A(k)/dk^n) \div n!$, where $A(k)$ represents the left-hand side of (1*). Now $K\sqrt{-1}$ is a solution of the new auxiliary by development of $A(k)$ in powers of $(k - \kappa)$; hence $u = \sin(Kx)$ and $u = \cos(Kx)$ are solutions of the new differential equation, as a comparison of coefficients demonstrates. This process constitutes a rigorous proof of (3).

‡ To avoid using imaginary powers of e, if that is desired, substitute $y = e^{\kappa x}[\cos(Kx) + \sqrt{-1}\sin(Kx)]u$, when the multiple root is imaginary, $k = \kappa + K\sqrt{-1}$.

These extensions of § 184 should be verified by the student by a direct check in each exercise.

Example	1	2	3
(1)	$y''' - y' = 0$	$y^{iv} + 6y''' + 12y'' + 8y' = 0$	$y''' + 8y = 0$
(1*)	$k^3 - k = 0$	$k^4 + 6k^3 + 12k^2 + 8k = 0$	$k^3 + 8 = 0$
$k =$	$0, 1, -1$	$0, -2, -2, -2$	$-2, 1 \pm \sqrt{3}\sqrt{-1}$
y	$c_1 + c_2e^x + c_3e^{-x}$	$c_1 + e^{-2x}(c_2 + c_3x + c_4x^2)$	$c_1e^{-2x} + e^x(c_2 \cos\sqrt{3}\,x + c_3 \sin\sqrt{3}\,x)$

189. Non-homogeneous Type. The non-homogeneous type

$$(1) \qquad \frac{d^ny}{dx^n} + a_1\frac{d^{n-1}y}{dx^{n-1}} + \cdots + a_{n-1}\frac{dy}{dx} + a_n = F(x)$$

cannot be solved in general by an extension of § 185. But in the majority of cases which actually arise in practice,* a sufficient method consists in *differentiating* both sides of (1) repeatedly until an elimination of the *right*-hand sides becomes possible. The new equation will be of higher order still:

$$(2) \qquad \frac{d^my}{dx^m} + A_1\frac{d^{m-1}y}{dx^{m-1}} + \cdots + A_{m-1}\frac{dy}{dx} + A_m = 0,$$

but its right-hand side is zero. Solve this equation by § 188 and then substitute the result in (1) for trial; of course there will be too many arbitrary constants; the superfluous ones are determined by comparison of coefficients, as in the examples below.

Example 1. $y''' + y' = \sin x$.

Differentiating both sides twice and adding the result to the given equation:

$$y^{v} + 2y''' + y' = 0.$$

* For more general methods, see any work on Differential Equations; *e.g.* Forsyth, *Differential Equations.*

The auxiliary equation $k^5 + 2k^3 + k = 0$ has the roots $k = 0$, $k = \pm\sqrt{-1}$ (twice). Hence we first write as a trial solution y_t the solution of the new equation: $y_t = c_1 + (c_2 + c_3x)\cos x + (c_4 + c_5x)\sin x$; substituting this in the given equation, we find $-2c_3\cos x - 2c_5\sin x = \sin x$, whence $c_3 = 0$ and $c_5 = -1/2$; substituting these values in the trial solution y_t gives the general solution of the given equation:

$$y = c_1 + c_2\cos x + (c_4 - x/2)\sin x.$$

EXERCISES

1. $y''' - 3y'' = 0.$ *Ans.* $y = c_1 + c_2x + c_3e^{3x}.$
2. $y''' - y'' - 4y' + 4y = 0.$ *Ans.* $y = c_1e^x + c_2e^{2x} + c_3e^{-2x}.$
3. $y^{\text{iv}} - 16y = 0.$ *Ans.* $y = c_1e^{2x} + c_2e^{-2x} + c_3\cos 2x + c_4\sin 2x.$
4. $y^{\text{iv}} - 6y'' + 9 = 0.$ *Ans.* $y = e^{x\sqrt{3}}(c_1 + c_2x) + e^{-x\sqrt{3}}(c_3 + c_4x).$
5. $y^{\text{v}} + 6y''' + 9y' = 0.$

   Ans. $y = c_1 + (c_2 + c_3x)\cos\sqrt{3}\,x + (c_4 + c_5x)\sin\sqrt{3}\,x.$
6. $y^{\text{vi}} - 16y''' + 64y = 0,$ $k = 2, 2, -1 \pm i\sqrt{3}, -1 \pm i\sqrt{3}.$

   Ans. $y = e^{2x}(c_1 + c_2x) + e^{-x}[(c_3 + c_4x)\cos\sqrt{3}\,x + (c_5 + c_6x)\sin\sqrt{3}\,x.$
7. $y'' - 5y' + 4y = e^{2x}.$ *Ans.* $y = c_1e^x - (1/2)e^{2x} + c_2e^{4x}.$
8. $3y'' + 4y' + y = \sin x.$
9. $y''' - 3y'' + 2y' = x.$
10. $y''' - y'' - 4y' + 4y = e^x.$
11. $y^{\text{iv}} - 5y'' + 4y = e^{2x}.$
12. Solve the equation $y''' + y' = 0$ by first setting $y' = p.$

Solve the following equations by setting $y' = p$ or else $y'' = q.$

13. $3y''' - 4y'' + y' = 0.$
14. $y''' + y'' + y' = 0.$
15. $y''' + y' = \sin x.$
16. $y''' + 3y'' + 2y' = e^x.$
17. $y^{\text{iv}} - y'' = 0.$
18. $y^{\text{iv}} + y'' = e^x.$

The following equations, though not linear, may be solved by first setting $y' = p$ or $y'' = q$ or $y''' = r.$

19. $y' = y'' + \sqrt{1 + y''^2}.$
20. $y'' + y'''x = (y'')^2x^4.$
21. $1 + x + x^2y''' = 0.$
22. $xy^{\text{iv}} + y''' = x^2.$
23. Solve the equation $x^2y'' + xy' - y = \log x.$

[Hint. Put $x = e^z$; then

$$\frac{dy}{dx} = \frac{dy}{dz}\cdot\frac{dz}{dx} = \frac{1}{x}\frac{dy}{dz}; \quad \frac{d^2y}{dx^2} = \frac{d}{dz}\left(\frac{1}{x}\frac{dy}{dz}\right)\cdot\frac{dz}{dx} = \frac{1}{x^2}\left(\frac{d^2y}{dz^2} - \frac{dy}{dz}\right);$$

so that the transformed equation is

$$\frac{d^2y}{dz^2} - y = z, \text{ whence } y = c_1e^z + c_2e^{-z} - z = c_1x + c_2x^{-1} - \log x.]$$

Solve the equations,

24. $x^2y'' - xy' - 3y = 0$. **25.** $xy'' - y' = \log x$.

26. $(x+1)^2 y'' - 4(x+1)y' + 6y = x$, $(x+1 = e^z)$.

27. $(a+bx)^2y'' + (a+bx)y' - y = \log(a+bx)$, $(a+bx = e^z)$.

28. $x^3y''' - 6y = 1 + x$.

190. Systems of Differential Equations. Let us finally consider systems of two equations, and let us suppose the equations to be linear in the derivatives, that is, to involve only the first powers of these derivatives.

191. Linear System of the First Order. Let the equations be

$$y' = ax + by + cz + d, \tag{1}$$

$$z' = a_1x + b_1y + c_1z + d_1, \tag{2}$$

where the coefficients are constant. We wish to determine y and z as functions of x.

Differentiating (1) with respect to x gives

$$y'' = a + by' + cz'; \tag{3}$$

then the elimination of z and z' between the three equations (1), (2), (3), gives a differential equation of the second order in y, which should be solved for y.

192. $dx/P = dy/Q = dz/R$. Here P, Q, and R are functions of x, y, z. Let λ, μ, ν be any multipliers, either constants or functions of x, y, z. Then, by the laws of algebra,

$$\frac{dx}{P} = \frac{dy}{Q} = \frac{dz}{R} = \frac{\lambda dx + \mu dy + \nu dz}{\lambda P + \mu Q + \nu R}. \tag{1}$$

Suppose that we can select from these ratios (or from these together with others obtainable from them by giving suitable values to λ, μ, ν) two equal ratios free from z, *i.e.* containing only x and y. Such an equation is an ordinary differential equation of the first order in x and y. Solving it, we obtain

$$f(x, y, c_1) = 0. \tag{2}$$

Suppose that a second pair of ratios can be found, free from another of the variables, say y. The result is an equation of the first order in x and z. Let its solution be

$$F(x, z, c_2) = 0. \tag{3}$$

Then (2) and (3) form the complete solution of the system. Conversely, differentiating (2) and (3) with respect to x, eliminating c_1 and c_2, and solving for $dx : dy : dz$, we find a system like (1). In selecting the second pair of ratios, the result (2) of the first integration may be utilized to eliminate the variable whose absence is desired.

EXAMPLE 1. $$dx/x^2 = dy/xy = dz/z^2.$$

The first two ratios give $dx/x = dy/y$, whence $y = c_1x$. Putting this value of y in $dy/xy = dz/z^2$ gives $dy/(c_1y^2) = dz/z^2$, so that

$$\frac{1}{c_1y} = \frac{1}{z} + c_2,$$

or, $z = c_1y + c_1c_2yz = x + c_2xz$. Hence the solutions are given by the two equations $y = c_1x$, $z = x + c_2xz$.

Interpreted geometrically, the solutions represent a family of planes and a family of hyperboloids. These are the ***integral surfaces*** of the differential equation. Each plane cuts each hyperboloid in a space curve, forming a doubly infinite system of curves, the ***integral curves*** of the differential equation. The system may be written $dx:dy:dz = x^2:xy:y^2$. But the direction cosines of the tangent to a space curve are proportional to dx, dy, dz. Thus the given equations define at each point a direction whose cosines are proportional to x^2, xy, y^2. Our solution is a system of curves having at each point the proper direction. What curve of the above system goes through (4, 2, 3)? What are the angles which the tangent to the curve at this point makes with the coordinate axes?

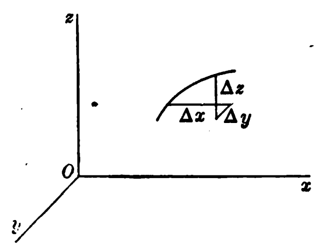

FIG. 88.

EXAMPLE 2. $$\frac{dx}{y-z} = \frac{dy}{z-x} = \frac{dz}{x-y}$$

Let $\lambda = \mu = \nu = 1$. Then each of the above fractions equal

$$\frac{dx + dy + dz}{0}.$$

But since the given ratios are in general finite, this gives

$$dx + dy + dz = 0, \quad \text{whence} \quad x + y + z = c_1.$$

Again, let $\lambda = x$, $\mu = y$, $\nu = z$. This gives

$$x\,dx + y\,dy + z\,dz = 0, \quad \text{whence} \quad x^2 + y^2 + z^2 = c_2.$$

Thus the integral surfaces are planes and spheres, and the integral curves are the circles in which they intersect.

In this example the multipliers λ, μ, ν have been chosen so as to get exact differentials.

EXAMPLE 3. $$\frac{dx}{x-y} = \frac{dy}{x+y} = \frac{dz}{z}.$$

The first two ratios are free from z and give

$$\text{arc tan } (y/x) = \log\,[c_1 x^2/\sqrt{x^2+y^2}].$$

Using the multipliers $\lambda = x$, $\mu = y$, $\nu = 0$, and equating the ratio thus obtained to the last of the given ratios, we find

$$\frac{x\,dx + y\,dy}{x^2+y^2} = \frac{dz}{z}, \quad \text{whence } x^2 + y^2 = c^2 z^2.$$

EXERCISES

1. $x\,dx/y^2 = y\,dy/x^2 = dz/z$. *Ans.* $x^4 - y^4 = c_1$; $z^2 = c_2\,(x^2 + y^2)$.

2. $dx/x = dy/y = -\,dz/z$. *Ans.* $yz = c_1$; $y = c_2 x$.

3. $dx/yz = dy/xz = dz/(x + y)$.
Ans. $z^2 = 2\,(x + y) + c_1$; $x^2 - y^2 = c_2$.

4. $dx/(y + z) = dy/(x + z) = dz\ \ (x + y)$.
Ans. $(x - y) = c_1\,(x - z)$
$(x - y)^2\,(x + y + z) = c_2$.

5. $dx/(x^2 + y^2) = dy/(2\,xy) = dz/(xz + yz)$.
Ans. $2\,y = c_1\,(x^2 - y^2)$; $x + y = c_2 z$.

6. $\dfrac{dy}{dx} = \dfrac{2\,xy}{x^2 - y^2 - z^2}$; $\dfrac{dz}{dx} = \dfrac{2\,xz}{x^2 - y^2 - z^2}$.
Ans. $y = c_1 z = c_2\,(x^2 + y^2 + z^2)$.

7. $\dfrac{dy}{dx} = \dfrac{z - 3x}{3y - 2z}; \; \dfrac{dz}{dx} = \dfrac{2x - y}{3y - 2z}.$

Ans. $x + 2y + 3z = c_1; \; x^2 + y^2 + z^2 = c_2.$

8. $dx = -ky\,dt; \; dy = kx\,dt.$

Ans. $x = A \cos kt + B \sin kt; \; y = A \sin kt - B \cos kt.$

9. $dx/dt = 3x - y; \; dy/dt = x + y.$

Ans. $x = (A + Bt)e^{2t}; \; y = (A - B + Bt)e^{2t}.$

10. Determine the curves in which the direction cosines of the tangent are respectively proportional to the coordinates of the point of contact; to the squares of those coordinates.

11. A particle moves in a plane so that the sum of the axial components of the speed always equals the sum of the coordinates of the particle, while the difference of the components is a constant k. Determine the possible paths. *Ans.* $x + y = c_1e^t; \; x - y = kt + c_2.$

12. If the particle in Exercise 11 is at (1, 1) when $t = 0$, where is it when $t = 5$? Approximately how far has it traveled?

TABLES

[Roman page numbers refer to the body of the text; italic page numbers refer to these *Tables.*]

TABLE I

SIGNS AND ABBREVIATIONS

1. *Elementary signs assumed known without explanation.*

$+$; $\pm$; $\mp$; $-$; $=$; $a \times b = a \cdot b = ab$; $a \div b = a/b = a : b = \dfrac{a}{b}$; a^2; a^3; a^n; $a^{-n} = 1/a^n$; $a^{1/n} = \sqrt[n]{a}$; $a^{p/q} = \sqrt[q]{a^p}$; $a^0 = 1$; ( ); [ ]; a', a'', ..., $a^{(n)}$ (accents); a_1, a_2, ..., a_n (subscripts).

2. *Other elementary signs:*

$\neq$, not equal to.	$\geqq$, greater than or equal to.
$>$, greater than.	$\leqq$, less than or equal to.
$<$, less than.	$n!$ (or $\lfloor n$), factorial $n = n(n-1) \cdots 3 \cdot 2 \cdot 1$.
q.p., approximately.	$\|a\|$, absolute or numerical value of a.

3. *Signs peculiar to The Calculus and its Applications:*

(*a*) *Given a plane curve $y = f(x)$ in rectangular coördinates (x, y);*
m = slope $= dy/dx = f'(x) = y'$ = first derivative; see p. 19.
[Also occasionally $D_x y$, f_x, $\dot{y}$, p, by some writers.]
α = angle between positive x-axis and curve $= \tan^{-1} m$.
Δy, $\Delta^2 y$, $\cdots$, $\Delta^n y$, first, second, $\cdots$, n^{th} differences (or increments) of y.
$dy = f'(x) \cdot \Delta x$, $d^2y = f''(x) \cdot \overline{\Delta x}^2$, $\cdots$, $d^n y = f^{(n)}(x) \cdot \overline{\Delta x}^n$, first, second, $\cdots$, n^{th} differentials of y.
r_r = relative rate of increase, or logarithmic derivative; see p. 114;
$= f'(x) \div f(x) = (dy/dx) \div y = d(\log y)/dx = r_p \div 100$.
r_p = percentage rate of increase $= 100 \cdot r_r$.
b = flexion $= d^2y/dx^2 = f''(x) = y''$ = second derivative; see p. 62.
$d^n y/dx^n = f^{(n)}(x) = y^{(n)} = n^{\text{th}}$ derivative.
K = curvature $= 1 \div R$; R = radius of curvature $= 1 \div K$; p. 140.

$\int f(x)\,dx$ = indefinite integral of $f(x)$; see p. 83.

$\int_a^b f(x)\,dx = \int_{x=a}^{x=b} f(x)\,dx$ = definite integral of $f(x)$; see p. 87.

s = length of arc; $s\Big]_{x=a}^{x=b}$ = arc between $x = a$ and $x = b$.

$A\Big]_a^b = A\Big]_{x=a}^{x=b}$ = area between $y = 0$, $y = f(x)$, $x = a$, $x = b$; see p. 90.

(*b*) *Given a curve $\rho = f(\theta)$ in polar coördinates (ρ, θ):*

$\psi = \angle$ (radius vector and curve) $= \text{ctn}^{-1}[(d\rho/d\theta) \div \rho]$
$= \text{ctn}^{-1}[d(\log \rho)/d\theta]$.

$\phi = \angle$ (circle about O and curve) $= \tan^{-1}[(d\rho/d\theta) \div \rho]$
$= \tan^{-1}[d(\log \rho)/d\theta]$.

$A\Big]_\alpha^\beta = A\Big]_{\theta=\alpha}^{\theta=\beta}$ = area between $\rho = f(\theta)$, $\theta = \alpha$, $\theta = \beta$; see p. 150.

(*c*) ***For problems in plane motion:***

s = distance.	v_x = horizontal speed = projection of $\boldsymbol{v}$ on Ox.
t = time.	v_y = vertical speed = projection of $\boldsymbol{v}$ on Oy.
m = mass.	j_x = horizontal acceleration = proj. of $\boldsymbol{j}$ on Ox.
v = speed.	j_y = vertical acceleration = proj. of $\boldsymbol{j}$ on Oy.
$\boldsymbol{v}$ = velocity (vector).	j_N = normal acc. = proj. of $\boldsymbol{j}$ on the normal.
$\boldsymbol{j}$ = acc. (vector).	j_T = tangential acc. = proj. of $\boldsymbol{j}$ on the tangent.
θ = angle (of rotation).	α = angular acceleration.
ω = angular speed.	g = acceleration due to gravity.

(*d*) ***Problems in space; functions $z = f(x, y, \cdots)$ of several variables***

Previous notations are generalized when possible without ambiguity, exceptions are

$$p = \partial x/\partial x = f_x; \quad q = \partial z/\partial y = f_y;$$

$$r = \partial^2 z/\partial x^2 = f_{xx}; \quad s = \partial^2 z/\partial x\,\partial y = f_{xy} = f_{yx}; \quad t = \partial^2 z/\partial y^2 = f_{yy}.$$

[The notation (dz/dx), used by some writers for $\partial z/\partial x$ is ambiguous.]

4. *Other letters commonly used with special meanings:*

π = ratio of circumference to diameter of circle = 3.14159….

e = base of Napierian (or hyperbolic) logarithms = 2.71828….

$M = \log_{10} e$ = modulus of Napierian to common logarithms = 0.434…

$\sum$ = "sum of such term as"; thus: $\sum_{i=1}^{i=n} a_i^2 = a_1^2 + a_2^2 + \cdots a_n^2$.

(α, β, γ), — direction angles of a line in space.

(l, m, n), — direction cosines; $l = \cos\alpha$, etc.

S. H. M. — simple harmonic motion.

ϵ or e, — eccentricity of a conic; *also* phase angle of a S. H. M.

a, — amplitude of a S. H. M.

(a, b), — semiaxes of a conic; (a, b, c), semiaxes of a conicoid.

Δ = difference (of two values of a quantity).

ρ = density; *also* radius vector, radius of curvature, radius of gyration.

5. *Trigonometric, logarithmic, hyperbolic, and other transcendental functions:* See *Tables*, II, A; II, F, 3; II, G; II, H; and consult Index.

6. *Inverse function notations:*

If $y = f(x)$, then $f^{-1}(y) = x$; f^{-1} denotes an *inverse function.* [This notation is ambiguous; confusion with $\{f(x)\}^{-1} = 1 \div f(x)$.]

$\sin^{-1} x$ or arc sin x, — inverse of $\sin x$, or anti-sine of x, or **arc sine x**, or angle whose sine is x. [Other inverse trigonometric functions, and hyperbolic functions, follow the same notations. See *Tables*, II, G, 18; H, 7.]

TABLE II

STANDARD FORMULAS

A. Exponents and Logarithms.

(The letters B, b, etc. indicate *base;* L, l, ⋯ indicate *logarithm;* N, n, ⋯ indicate *number;* base arbitrary when not stated. See § 59, p. 99.)

Laws of Exponents	Rules of Logarithms
(1) $N = B^L$; in particular $1 = B^0$; $B = B^1$; $1/B = B^{-1}$.	(1)′ $L = \log_B N$, *i.e.* $N = B^{\log_B N}$; and: $\log 1 = 0$; $\log_B B = 1$; $\log_B (1/B) = -1$.
(2) $B^L \cdot B^l = B^{L+l}$.	(2)′ $\log (N \cdot n) = \log N + \log n$.
(3) $B^L \div B^l = B^{L-l}$.	(3)′ $\log (N \div n) = \log N - \log n$.
(4) $(B^L)^n = B^{nL}$.	(4)′ $\log (N^n) = n \log N$.
(5) $N = B^L$, $B = b^k$, $N = b^{kL}$.	(5)′ $\log_b N = \log_b B \cdot \log_B N$.

$B = e$, $b = 10$	gives	$k = 0.4342945 = M = \log_{10} e$;	$\log_{10} N = M \cdot \log_e N$.
$B = 10$, $b = e$	gives	$k = 2.302585 = 1 \div M = \log_e 10$;	$\log_e N = (1 \div M) \log_{10} N$.
$b = N$	gives	$L = 1/k$, $1 = \log_b B \cdot \log_B b$;	*e.g.*, $\log_e 10 = 1 \div \log_{10} e$.
$L = x$	gives	$10^x = e^{x \div M}$;	$e^x = 10^{Mx}$.
$N = x$	gives	$\log_{10} x = M \cdot \log_e x$;	$\log_e x = (1 \div M) \log_{10} x$.

(6) $y = cx^n$ gives $v = nu + k$, $u = \log_{10} x$, $v = \log_{10} y$, $k = \log_{10} c$.

(7) $y = ce^{ax}$ gives $v = mx + k$, $v = \log_{10} y$, $m = a \log_{10} e = aM$, $k = \log_{10} c$.

B. Factors.

(1) $a^2 - b^2 = (a - b)(a + b)$. (2) $(a \pm b)^2 = a^2 \pm 2ab + b^2$.

(3) $a^n - b^n = (a - b)(a^{n-1} + a^{n-2}b + a^{n-3}b^2 + \cdots + b^{n-1})$.

(4) $a^{2n+1} + b^{2n+1} = (a + b)(a^{2n} - a^{2n-1}b + \cdots + b^{2n})$.

See also *Tables*, IV, Nos. 16, 20, 21, 49, 50.

(5) *Polynomials:* if $f(a) = 0$, $f(x)$ has a factor $x - a$; in general: $f(x) \div (x - a)$ gives remainder $f(a)$.

(6) $(a \pm b)^n = a^n \pm \frac{n}{1} a^{n-1}b + \frac{n(n-1)}{1 \cdot 2} a^{n-2}b^2 + \cdots + (\pm 1)^n b^n$.
See II, E, 1, p. 7.

C. Solution of Equations.

(1) $ax^2 + bx + c = 0$, roots: $x = -\frac{b}{2a} \pm \frac{\sqrt{b^2 - 4ac}}{2a} = -\frac{b}{2a} \pm \frac{\sqrt{D}}{2a}$,
where

$D = b^2 - 4ac$; roots of (1) are $\left\{\begin{matrix}\text{real}\\ \text{coincident}\\ \text{imaginary}\end{matrix}\right\}$ when $D \left\{\begin{matrix}>0\\ =0\\ <0\end{matrix}\right\}$.

(2) $x^n + p_1x^{n-1} + p_2x^{n-1} + \cdots + p_{n-1}x + p_n = 0$. Roots: $x_1, x_2, \cdots, x_n$;
then $\sum x_i = -p_1$, $\sum_{i \neq j} x_ix_j = p_2$, $\sum_{i \neq j \neq k} x_ix_jx_k = -p_3$, etc.

(3) $f(x) - \phi(x) = 0$: roots given by intersections of $y = f(x)$, $y = \phi(x)$. (Logarithmic chart often useful.) Find roots approximately; redraw figure on larger scale near intersection. (*Generalized Horner Process.*)

(4) *Simultaneous Equations:* $f(x, y) = 0$, $\phi(x, y) = 0$: roots (x, y) are points of intersection; redraw on larger scale as in (3).

(5) *Linear Equations:*

(*a*) 2 equations in 2 unknowns: $\left\{\begin{matrix} a_1x + b_1y = c_1 \\ a_2x + b_2y = c_2 \end{matrix}\right\}$.

Solutions: $x = \begin{vmatrix} c_1 b_1 \\ c_2 b_2 \end{vmatrix} \div \begin{vmatrix} a_1 b_1 \\ a_2 b_2 \end{vmatrix} = (c_1b_2 - c_2b_1) \div (a_1b_2 - a_2b_1)$,

$$y = \begin{vmatrix} a_1 c_1 \\ a_2 c_2 \end{vmatrix} \div \begin{vmatrix} a_1 b_1 \\ a_2 b_2 \end{vmatrix} = (a_1c_2 - a_2c_1) \div (a_1b_2 - a_2b_1).$$

(*b*) n equations in n unknowns: $a_i x_1 + b_i x_2 + \cdots + k_i x_n = p_i$; $i = 1, 2, \cdots, n$.

Solutions: $$x_i = \begin{vmatrix} a_1 & b_1 & \cdots & p_1 & \cdots & k_1 \\ a_2 & b_2 & \cdots & p_2 & \cdots & k_2 \\ \cdot & \cdot & & \cdot & & \cdot \\ \cdot & \cdot & & \cdot & & \cdot \\ \cdot & \cdot & & \cdot & & \cdot \\ a_n & b_n & \cdots & p_n & \cdots & k_n \end{vmatrix} \div D \quad \left\{ \begin{matrix}\text{Column of } p\text{'s replaces column of} \\ \text{coefficients of } x_i. \end{matrix} \right\}$$

where

$$D = \begin{vmatrix} a_1 & b_1 & \cdots & k_1 \\ a_2 & b_2 & \cdots & k_2 \\ \cdot & \cdot & & \cdot \\ \cdot & \cdot & & \cdot \\ \cdot & \cdot & & \cdot \\ a_n & b_n & \cdots & k_n \end{vmatrix} = a_1 \begin{vmatrix} b_2 & \cdots & k_2 \\ b_3 & \cdots & k_3 \\ \cdot & & \cdot \\ \cdot & & \cdot \\ \cdot & & \cdot \\ b_n & \cdots & k_n \end{vmatrix} - a_2 \begin{vmatrix} b_1 & \cdots & k_1 \\ b_3 & \cdots & k_3 \\ \cdot & & \cdot \\ \cdot & & \cdot \\ \cdot & & \cdot \\ b_n & \cdots & k_n \end{vmatrix} + \cdots + (-1)^{n-1} a_n \begin{vmatrix} b_1 & \cdots & k_1 \\ b_2 & \cdots & k_2 \\ \cdot & & \cdot \\ \cdot & & \cdot \\ \cdot & & \cdot \\ b_{n-1} & & k_{n-1} \end{vmatrix}.$$

[Coefficient of a_i skips ith row of D. The last formula is a general definition of a **determinant.**]

D. Applications of Algebra.

1. *Interest.* (P = principal; p = rate per cent; $r = p \div 100$; n = number of years; A_n = amount after n years.)

(*a*) Simple interest: $A_n = P(1 + nr)$.

(*b*) Yearly compound interest: $A_n = P \cdot (1 + r)^n$.

(*c*) Semiannually compounded: $A_n = P(1 + r/2)^{2n}$.

(*d*) Compounded once each mth part of year: $A_n = P(1 + r/m)^{mn}$.

(*e*) Continuously compounded: $A_n = P \lim_{m \doteq \infty} (1 + r/m)^{mn} = Pe^{nr}$.

2. *Annuities. Depreciation.* (I = yearly income (or depreciation or payment or charge); n = number of years annuity, or depreciation, runs.)

(*a*) Present worth P of yearly annuity I:

$$P = I[(1 + r)^n - 1] \div [r(1 + r)^n].$$

(*b*) Annuity I purchasable by present amount P; or, yearly depreciation I of plant of value P:

$$I = P[r(1 + r)^n] \div [(1 + r)^n - 1].$$

(*c*) *Final* value A_n of n yearly payments:

$$A_n = I(1 + r)[(1 + r)^n - 1] \div r.$$

3. *Permutations* $P_{n,r}$, *and Combinations* $C_{n,r}$, of n things r at a time, without repetitions:

(*a*) $P_{n,r} = n(n-1) \cdots (n-r+1) = n! \div (n-r)!$

(*b*) $C_{n,r} = P_{n,r} \div r! = [n(n-1) \cdots (n-r+1)] \div r!$

4. *Chance and Probability.*

(*a*) Chance of an event $\doteq$ (number of favorable cases) $\div$ (total number of trials) $\leqq 1$.

Chance of successive (independent) events = product of separate chances $\leqq 1$.

Chance of at least one of several (independent) events = sum of separate chances.

(*b*) Probable value v of an observed quantity:

$v = \left(\sum m_i\right) \div n =$ arithmetic mean of n measurements m_1, m_2, $\cdots$, m_n; probable error in $v = \pm .6745 \sqrt{\left(\sum (v - m_i)^2\right) \div n(n-1)}$.

(If the observations are unequally reliable, count each one a number of times, p_i, which represents its estimated reliability; p_i = "weight" of m_i).

(*c*) Probable value of k in formula $v = kx$:

$k = \sum x_i v_i \div \sum x_i^2$, from n measurements (x_1, v_1), (x_2, v_2), $\cdots$, (x_n, v_n); probable error in $k = \pm .6745 \sqrt{\sum (kx_i - v_i)^2 \div (n-1) \sum x_i^2}$. See Exs. 37, p. 58; 28, p. 309.

(*d*) Probable values of k, l, m, $\cdots$, in formula $v = kx + ly + mz + \cdots$ are solutions of the equations:

$$
\begin{array}{l}
k \sum x_i^2 + l \sum x_i y_i + m \sum x_i z_i + \cdots = \sum x_i v_i \\
k \sum x_i y_i + l \sum y_i^2 + m \sum y_i z_i + \cdots = \sum y_i v_i \\
k \sum x_i z_i + l \sum y_i z_i + m \sum z_i^2 + \cdots = \sum z_i v_i \\
\cdot \qquad \cdot \qquad \cdot \qquad \cdot \\
\cdot \qquad \cdot \qquad \cdot \qquad \cdot \\
\cdot \qquad \cdot \qquad \cdot \qquad \cdot
\end{array}
$$

See also Exs. 37–42, p. 58, Example 2, p. 292, and Exs. 24–31, p. 308. (*Rules for Least Squares.* See also *Observational Errors*, No. III, J.)

E. Series.

1. *Binomial Theorem: Expansion of* $(a+b)^n$.

(*a*) n a positive integer: $(a+b)^n = a^n + \sum_{r=1}^{r=n} C_{n,r} a^{n-r} b^r$;

[$C_{n,r}$: see No. II, D, 3, p. 6, and also II, B, 6, p. 4.]

(*b*) n fractional or negative, $|a| > |b|$:

$$(a+b)^n = a^n + \frac{n}{1!}a^{n-1}b + \frac{n(n-1)}{2!}a^{n-2}b^2 + \cdots + C_{n,r}a^{n-r}b^r + \cdots \text{ (forever)}$$

(*c*) Special cases:

$$(1 \pm x)^n = 1 \pm \frac{n}{1!}x + \frac{n(n-1)}{2!}x^2 \pm \frac{n(n-1)(n-2)}{3!}x^3 + \cdots; \ (|x|<1).$$

$$\frac{1}{1 \pm x} = (1 \pm x)^{-1} = 1 \mp x + x^2 \mp x^3 + x^4 \mp \cdots; \ (|x|<1). \quad \text{(Geometric progression.)}$$

$$\sqrt{1 \pm x} = (1 \pm x)^{1/2} = 1 \pm \frac{1}{2}x - \frac{1}{2^2 \cdot 2!}x^2 \pm \frac{1 \cdot 3}{2^3 \cdot 3!}x^3 - \cdots; \ (|x|<1).$$

$$\frac{1}{\sqrt{1 \pm x}} = (1 \pm x)^{-1/2} = 1 \mp \frac{1}{2}x + \frac{1 \cdot 3}{2^2 \cdot 2!}x^2 \mp \frac{1 \cdot 3 \cdot 5}{2^3 \cdot 3!}x^3 + \cdots; \ (|x|<1).$$

2. Arithmetic series: $a + (a+d) + (a+2d) + \cdots + (a+(n-1)d)$; last term $= l = a + (n-1)d$; sum $= s = n(a+l)/2$.

3. Geometric series: $a + ar + ar^2 + ar^3 + \cdots$.

(*a*) n terms: $l = ar^{n-1}$; $s = \dfrac{rl-a}{r-1} = a\dfrac{r^n-1}{r-1}$.

(*b*) infinite series, $|r|<1$: $s = a/(1-r)$.

4. $1 + 2 + 3 + 4 + \cdots + (n-1) + n = n(n+1)/2$.

5. $2 + 4 + 6 + 8 + \cdots + (2n-2) + 2n = n(n+1)$.

6. $1 + 3 + 5 + 7 + \cdots + (2n-3) + (2n-1) = n^2$.

7. $1^2 + 2^2 + 3^2 + \cdots + (n-1)^2 + n^2 = n(n+1)(2n+1) \div 3!$

8. $1^3 + 2^3 + 3^3 + \cdots + (n-1)^3 + n^3 = [n(n+1)/2]^2$.

9. $1 + 1/1! + 1/2! + 1/3! + \cdots = \lim_{n\to\infty}\left(1 + \frac{1}{n}\right)^n = e = 2.71828\cdots$.

10. $e^x = 1 + x/1! + x^2/2! + x^3/3! \cdots$; (all x); $a^x = e^{x \log_e a}$.

11. $\log_e(1 \pm x) = \pm x - x^2/2 \pm x^3/3 - x^4/4 \pm x^5/5 - \cdots$; $(-1 < x < +1)$.

12. $\log_e[(1+x)/(1-x)] = 2[x + x^3/3 + x^5/5 + \cdots]$; $(-1 < x < +1)$.

[Computation of $\log N$: set $N = (1+x)/(1-x)$; then $x = (N-1)/(N+1)$; use II, A, 5′.]

13. $\sin x = x/1! - x^3/3! + x^5/5! - x^7/7! + \cdots$; (all x).

14. $\cos x = 1 - x^2/2! + x^4/4! - x^6/6! + \cdots$; (all x).

15. $\tan x = x + x^3/3 + 2x^5/15 + 17x^7/315 + \cdots$; $(|x| < \pi/2)$.

General term: $2^{2n}(2^{2n}-1)B_{2n-1} \div (2n)!$; see B_n, *Tables*, V, N, p. *60*.

16. $\operatorname{ctn} x = 1/x - x/3 - x^3/45 - \sum 2B_{2n-1}(2x)^{2n-1} \div (2n)!$; $(0 < |x| < \pi)$.

17. $\sec x = 1 + x^2/2! + 5x^4/4! + \sum [B_{2n}x^{2n}/(2n)!]$; $(|x| < \pi/2)$.

18. $\csc x = 1/x + x/3! + \sum [2(2^{2n+1}-1)B_{2n+1}x^{2n+1}/(2n+2)!]$; $(0 < |x| < \pi)$.

19. $\sin^{-1} x = \pi/2 - \cos^{-1} x = x + x^3/(2\cdot 3) + 1\cdot 3x^5/(2\cdot 4\cdot 5) + \cdots$; $(|x| < 1)$.

20. $\tan^{-1} x = \pi/2 - \operatorname{ctn}^{-1} x = x - x^3/3 + x^5/5 - x^7/7 + \cdots$; $(|x| < 1)$.

21. $(e^x + e^{-x})/2 = \cosh x = 1 + x^2/2! + x^4/4! + x^6/6! + \cdots$; (all x).

22. $(e^x - e^{-x})/2 = \sinh x = x + x^3/3! + x^5/5! + x^7/7! + \cdots$; (all x).

23. $e^{-x^2} = 1 - x^2 + x^4/2! - x^6/3! + x^8/4! - \cdots$; (all x).

24. $f(x) = f(a) + f'(a)(x-a) + f''(a)(x-a)^2/2! + \cdots + f^{(n-1)}(a)(x-a)^{n-1}/(n-1)! + E_n$.

Taylor's Theorem; *Remainder* E_n: $|E_n| \leq [\text{Max. } |f^{(n)}(x)|]\,|(x-a)^n| \div n!$; $E_n = f^n[a + p(x-a)](x-a)^n \div n!$; $E_n = (1-p)^{n-1}f^{(n)}[a + p(x-a)](x-a)^n/n!$; $|p| < 1$.

Set $a = 0$: $f(x) = f(0) + f'(0)x + f''(0)x^2/2! + \cdots + f^{(n-1)}(0)x^{n-1}/(n-1)! + E_n$; [*Maclaurin*].

Set $x = r + h$, $a = r$: $f(r+h) = f(r) + hf'(r) + h^2f''(r)/2! + \cdots + E_n$.

25. $f(x+h, y+k) = f(x, y) + [hf_x(x, y) + kf_y(x, y)] + [h^2f_{xx} + 2hkf_{xy} + k^2f_{yy}] \div 2! + \cdots + E_n$;

$|E_n| \leq M(|h| + |k|)^n \div n!$, M = maximum of absolute values of all n^{th} derivatives.

26. If $f(x) = a_0/2 + a_1\cos x + a_2\cos 2x + a_3\cos 3x + \cdots + b_1\sin x + b_2\sin 2x + b_3\sin 3x + \cdots$; $(-\pi < x < +\pi)$.

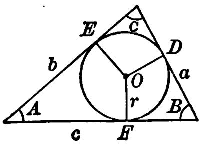
$$a_n = \frac{1}{\pi}\int_{x=-\pi}^{x=+\pi} f(x)\cos nx\,dx;\quad b_n = \frac{1}{\pi}\int_{x=-\pi}^{x=\pi} f(x)\sin nx\,dx.$$ **Fourier Theorem**

F. Geometric Magnitudes. Mensuration.

l = length (or perimeter); A = area; V = volume.

	Dimensions or Equations	Formulas

1. Triangle.



Dimensions or Equations. Sides: a, b, c. Angles: A, B, C.
Altitude from A on $a = h_a$.

$s = (a+b+c)/2$;
$\pi = A + B + C = 180°$;
$r = \sqrt{(s-a)(s-b)(s-c) \div s}$
$= (s-a)\tan(A/2)$;
$c = b\cos A + a\cos B$;
$c^2 = a^2 + b^2 - 2ab\cos C$.

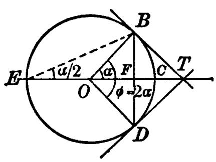
Formulas.
$l = a + b + c = 2s$;
$A = ah_a/2 = bh_b/2 = ch_c/2$
$= (1/2)ab\sin C$, etc.
$= rs = \sqrt{s(s-a)(s-b)(s-c)}$;
$\frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}$;
$\tan\frac{B-C}{2} = \frac{b-c}{b+c}\operatorname{ctn}\frac{A}{2}$.

2. Trapezoid.

Dimensions or Equations. h = height. b_1, b_2 = bases.

Formulas. $A = h(b_1 + b_2)/2$.

3. Circle.

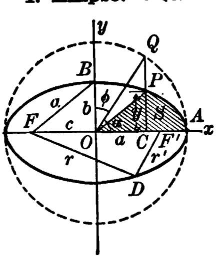


$\angle OEB = \alpha/2$;
$\angle OBT = 90°$;
$\angle FBT = \alpha$;
$\angle FBO = 90° - \alpha$
$= \angle FTB$;

Dimensions or Equations.
r = radius; d = diameter;
$\alpha = COB$ at center
$= \frac{\text{arc } CB}{r}$ (radians)
$= \frac{180}{\pi}\frac{\text{arc } CB}{r}$ (degrees);
$\alpha/2 = CEB$, $\phi = 2\alpha = DOB$;
$\sin\alpha = FB \div r = 1 \div \csc\alpha$;
$\cos\alpha = OF \div r = 1 \div \sec\alpha$;
$\tan\alpha = TB \div r = 1 \div \operatorname{ctn}\alpha$;
$\operatorname{vers}\alpha = FC \div r = 1 - \cos\alpha$;
$\operatorname{ex\,sec}\alpha = CT \div r = \sec\alpha - 1$.
$\tan(\alpha/2) = BF \div EF = \sin\alpha/(1+\cos\alpha)$;
$\sin(\alpha/2) = BF \div EB = \sqrt{(1-\cos\alpha)/2}$;
$\cos(\alpha/2) = EF \div EB = \sqrt{(1+\cos\alpha)/2}$.

Formulas.
$l = 2\pi r = \pi d = 2A/r$;
$A = \pi r^2 = \pi d^2/4 = l r/2$;
arc $CB = r \cdot \alpha$, (α in radians)
$= \pi r\alpha/180$, (α in degrees);
Chord $DB = 2r\sin\alpha$
$= 2r\sin(\phi/2)$;
Sector $ODCB = \frac{\alpha}{180}\pi r^2$, ($\alpha$ in degrees);
Triangle $DOB = r^2\sin\alpha\cos\alpha$
$= (1/2)r^2\sin 2\alpha$;
Segment $DFBC = r^2[\pi\alpha/180$
$- (\sin 2\alpha)/2]$.

4. Ellipse. $e < 1$.



$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, (origin at O).
or $\rho = \frac{p}{1 - e\cos\theta}$, (pole at F);
Foci, F, F'; Center; O.

Dimensions or Equations.
a, b, semiaxes; r, r', radii.
$c = \sqrt{a^2 - b^2}$;
$e = c/a = \sqrt{a^2 - b^2}/a$, (eccentricity);
$p = b^2/c = a(1 - e^2)/e$;
$\alpha = \tan^{-1}\left(\frac{ay}{bx}\right)$ = eccentric angle;
$x = a\cos\alpha$, $y = b\sin\alpha$;
$x = a\cos\frac{2S}{ab}$, $y = b\sin\frac{2S}{ab}$;
$x = a\sin\phi$, $y = b\cos\phi$;
$\phi = \pi/2 - \alpha$.

Formulas.
$r + r' = \text{const.} = 2a$. $A = \pi ab$;
$S = OAP = \frac{ab}{2}\alpha = \frac{ab}{2}\cos^{-1}\frac{x}{a}$;
Arc $AP = \int_x^a \sqrt{\frac{a^2 - e^2x^2}{a^2 - x^2}}\,dx$ [*Tables.*]
$= a\int_0^\alpha \sqrt{1 - e^2\cos^2\alpha}\,d\alpha$:
where $\cos\alpha = x/a$.
Arc $BP = \int_0^x \sqrt{\frac{a^2 - e^2x^2}{a^2 - x^2}}\,dx$
$= aE\left(\frac{x}{a}, e\right)$
$= a\int_0^\phi \sqrt{1 - e^2\sin^2\phi}\,d\phi$
$\phi = \pi/2 - \alpha$; $\sin\phi = x/a$.

	Dimensions or Equations	Formulas
5. Hyperbola. $e>1$; 	a, b: semiaxes; r, r': radii; $c=\sqrt{a^2+b^2}$; $e=c/a=\sqrt{a^2+b^2}/a$; $p=b^2/c=a(e^2-1)/e$. $\frac{x^2}{a^2}-\frac{y^2}{b^2}=1$, or $\rho=\frac{p}{1-e\cos\theta}$, (origin at O) (pole at F). Foci: F, F'	$r'-r=$ const. $=2a$; $S=$Sector $OVP=\frac{ab}{2}\log\left(\frac{x}{a}+\frac{y}{b}\right)$ $=\frac{ab}{2}\cosh^{-1}\left(\frac{x}{a}\right)=\frac{ab}{2}\sinh^{-1}\left(\frac{y}{b}\right)$; $x=a\cosh\frac{2S}{ab}$, $y=b\sinh\frac{2S}{ab}$; or if $\tan\phi=\sinh\frac{2S}{ab}$, $x=a\sec\phi$, $y=b\tan\phi$.
6. Parabola. $e=1$. 	$p=LN/2$; $LN=$ latus rectum. $OF=p/2=LN/4$. $y^2=2px$, (origin at O); $\rho=\frac{p}{1-\cos\theta}$, (pole at F). Focus: F	Area $ONPM=\frac{2}{3}\sqrt{2}\,x^{3/2}p^{1/2}$; Arc $OP=\int_{y=0}^{y=y}\sqrt{1+(y/p)^2}dy$. (See *Tables*, p. 40, No. 46 (a).
7. Prism.	$B=$ area of base; $h=$ height.	$V=B\cdot h$.
8. Prismoid (§ 124, p. 202).	$B=$ lower base (area); $M=$ middle section; $T=$ upper base; $h=$ height.	$V=\frac{h}{6}(B+4M+T)$. (See also *Tables*, IV, G, p. 47.)

[The volume of each of the solids mentioned below, except (16), follows this formula, though not all are prismoids.]

9. Pyramid (any sort).	$A=$ area of base; $h=$ height.	$V=A\cdot h/3$.
10. Right Circular Cylinder.	$r=$ radius of base; $h=$ height; $B=$ base (area).	A (curved) $=2\pi rh$; A (total) $=2\pi rh+2\pi r^2$; $V=\pi r^2h=Bh$.

	Dimensions or Equations	Formulas
11. Right Circular Cone. See Fig. 19, p. 75. $\tan\alpha = r/h$; $\cos\alpha = h/s$; $\sin\alpha = r/s$.	r = radius of base; h = height; B = base; s = slant height; α = half vertex angle.	$s = \sqrt{r^2+h^2}$; A (curved) $= \pi r\sqrt{r^2+h^2} = \pi rs$; A (total) $= \pi r(s+r)$; $V = \pi r^2h/3 = Bh/3$.
12. Frustum of Cone. B=lower base (area); T=upper base.	r = radius lower base; R = radius upper base; h = height; s=slant height.	$s = \sqrt{(R-r)^2+h^2}$; A (curved) $= \pi s(R+r)$; $V = \pi h(R^2+Rr+r^2)/3$.
13. Sphère. (a) *Entire Sphere.*	$(x-x_0)^2+(y-y_0)^2 + (z-z_0)^2 = r^2$; r = radius; d = diameter; C = great circle (area).	$A = 4\pi r^2 = \pi d^2 = 4C$; $V = 4\pi r^3/3 = \pi d^3/6 = A\cdot r/3 = 4Cr/3$.
(b) *Spherical Segment.* Other notations as above.	a = radius of base of segment; h = height of segment.	$a^2 = h(2r-h)$; $A = 2\pi rh = \pi(a^2+h^2)$; $V = \pi h(3a^2+h^2)/6 = \pi h^2(3r-h)/3$.
(c) *Spherical Zone.*	h = height of zone; a, b = radii of bases.	$A = 2\pi rh$; $V = \pi h(3a^2+3b^2+h^2)/6$.
(d) *Spherical Lune.*	α = angle of lune (degrees).	$A = \pi r^2\alpha/90$.
(e) *Spherical Triangle.* Sides α, β, γ. Angles A, B, C. $k = \sqrt{[\sin(s-\alpha)\sin(s-\beta)\sin(s-\gamma)]/\sin s}$; $K = \sqrt{-\cos S/[\cos(S-A)\cos(S-B)\cos(S-C)]}$.	$E = A+B+C-180°$; $S = (A+B+C)/2$; $s = (\alpha+\beta+\gamma)/2$.	$A = \pi r^2 E/180$; $\frac{\sin A}{\sin\alpha} = \frac{\sin B}{\sin\beta} = \frac{\sin C}{\sin\gamma}$; $\cos\alpha = \cos\beta\cos\gamma + \sin\beta\sin\gamma\cos A$; $\cos A = -\cos B\cos C + \sin B\sin C\cos\alpha$; $\tan(A/2) = k/\sin(s-\alpha)$; $\tan(\alpha/2) = K\cos(S-A)$.
14. Ellipsoid. Semiaxes, a, b, c.	$x^2/a^2+y^2/b^2+z^2/c^2 = 1$.	$V = 4\pi abc/3$.
15. Paraboloid of Revolution. $x^2+y^2=2pz$.	r = radius of base; h = height.	$V = \pi r^2h/2 = \pi ph^2$.
16. Anchor Ring. $\sqrt{x^2+y^2}\pm\sqrt{r^2-z^2}=R$.	r = radius, generating circle; R = mean radius of ring.	$A = 4\pi^2Rr$; $V = 2\pi^2Rr^2$.

H. Hyperbolic Functions.

1. *Definitions.* (See figures III, E, J_2, pp. *22*, *30*; and V, C, p. *54*.

$\sinh x = (e^x - e^{-x})/2$; $\cosh x = (e^x + e^{-x})/2$;

$\tanh x = \sinh x/\cosh x = (e^x - e^{-x})/(e^x + e^{-x})$;

$\operatorname{ctnh} x = 1/\tanh x$; $\operatorname{sech} x = 1/\cosh x$; $\operatorname{csch} x = 1/\sinh x$.

ϕ = Gudermannian of $x = gd\, x = \tan^{-1}(\sinh x)$; $\tan\phi = \sinh x$.

$$= \tan^{-1}[(e^x - e^{-x})/2] = 2\tan^{-1} e^x - \pi/2$$

2. $\cosh^2 x - \sinh^2 x = 1$. 3. $1 - \tanh^2 x = \operatorname{sech}^2 x$.

4. $1 - \operatorname{ctnh}^2 x = \operatorname{csch}^2 x$.

5. $\sinh(x \pm y) = \sinh x \cosh y \pm \cosh x \sinh y$.

6. $\cosh(x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y$.

7. $y = \sinh^{-1} x = \arg \sinh x =$ inverse hyperbolic sine, if $x = \sinh y$ [Similar inverse forms corresponding to $\cosh x$, $\tanh x$, etc.]

8. $\sinh^{-1} x = \cosh^{-1} \sqrt{x^2+1} = \operatorname{csch}^{-1}(1/x) = \log(x + \sqrt{x^2+1})$.

9. $\cosh^{-1} x = \sinh^{-1} \sqrt{x^2-1} = \operatorname{sech}^{-1}(1/x) = \log(x + \sqrt{x^2-1})$.

10. $\tanh^{-1} x = \operatorname{ctnh}^{-1}(1/x) = (1/2) \log[(1+x)/(1-x)]$.

11. If $\phi = gd\, x$, $\sinh x = \tan \phi$, $\cosh x = \operatorname{ctn} \phi$, $\tanh x = \sin \phi$.

I. a. Plane Analytic Geometry

[(x, y) or (a, b) denote a point; (x_1, y_1) and (x_2, y_2) two points; etc.]

1. Distance $l = P_1P_2 = \sqrt{(x_2-x_1)^2 + (y_2-y_1)^2} = \sqrt{\overline{\Delta x}^2 + \overline{\Delta y}^2}$.

2. Projection of P_1P_2 on $Ox = \Delta x = x_2 - x_1 = l \cos \alpha$, where
$$\alpha = \angle(Ox, P_1P_2).$$

3. Projection of P_1P_2 on $Oy = \Delta y = y_2 - y_1 = l \sin \alpha$.

4. Slope of $P_1P_2 = \tan \alpha = (y_2 - y_1)/(x_2 - x_1) = \Delta y/\Delta x$.

5. Division point of P_1P_2 in ratio r: $(x_1 + r\,\Delta x,\ y_1 + r\,\Delta y)$.

6. Equation $Ax + By + C = 0$: straight line.

(a) $y = mx + b$: slope, m; y-intercept, b.

(b) $y - y_0 = m(x - x_0)$: slope, m; passes through (x_0, y_0).

(c) $(y-y_1)/(y_2-y_1) = (x-x_1)/(x_2-x_1)$: passes through (x_1, y_1), (x_2, y_2).

(d) $x \cos \alpha + y \cos \beta = p$: distance to origin, p; $\alpha = \angle(Ox, n)$; $\beta = \angle(Oy, n)$; n = normal through origin.

[General equation $Ax + By + C = 0$ reduces to this on division by $\sqrt{A^2 + B^2}$.]

7. Angle between lines of slopes m_1, $m_2 = \tan^{-1}[(m_1 - m_2)/(1 + m_1m_2)]$. [Parallel, if $m_1 = m_2$; perpendicular, if $1 + m_1m_2 = 0$, *i.e.* if $m_1 = -1/m_2$.]

8. Transformation $x = x' + h$, $y = y' + k$. [Translation to (h, k).]

9. Transformation $x = cx'$, $y = ky'$. [Increase of scale in ratio c on x-axis; in ratio k on y-axis.]

10. Transformation, $x = x' \cos \theta - y' \sin \theta$, $y = x' \sin \theta + y' \cos \theta$. [Rotation of axes through angle θ.]

11. Transformation to polar coördinates (ρ, θ): $x = \rho \cos \theta$, $y = \rho \sin \theta$. Reverse transformation: $\rho = \sqrt{x^2 + y^2}$, $\theta = \tan^{-1}(y/x)$.

12. *Circle:* $(x-a)^2+(y-b)^2=r^2$; center, (a, b); radius, r; or $(x-a)=r\cos\theta$, $(y-b)=r\sin\theta$. (θ variable.)

13. *Parabola:* $y^2=2px$: vertex at origin; latus rectum $2p$.

14. *Ellipse:* $x^2/a^2+y^2/b^2=1$: center at origin; semiaxes, a, b. (See II, F, 4, p. *9*.)

15. *Hyperbola:* $x^2/a^2-y^2/b^2=1$; center at origin; semiaxes, a, b; asymptotes, $x/a \pm y/b=0$. See II, F, 5, p. *10*.

(*a*) If $a=b$, $x^2-y^2=a^2$; retangular hyperbola.

(*b*) $xy=k$, rectangular hyperbola; asymptotes: the axes.

(*c*) $y=(ax+b)/(cx+d)$, rectangular hyperbola; asymptotes: $x=-d/c$, $y=a/c$.

16. *Parabolic Curves:* $y=a_0+a_1x+a_2x^2+\cdots+a_nx^n$.
[Graph of polynomial; see also Figs. A, B, pp. *19*, *20*.]

17. **Lagrange Interpolation Formula.** **Given $y=f(x)$,** the polynomial approximation of degree $n-1$ [parabolic curve through n points, (x_1, y_1), (x_2, y_2), $\cdots$, (x_n, y_n)] is

$$y=P(x)=y_1p_1(x)+y_2p_2(x)+\cdots+y_np_n(x),$$

where the polynomials $p_1(x)$, $p_2(x)$, $\cdots$, $p_n(x)$ are

$$p_i(x)=\frac{(x-x_1)(x-x_2)\cdots(x-x_{i-1})(x-x_{i+1})\cdots(x-x_n)}{(x_i-x_1)(x_i-x_2)\cdots(x_i-x_{i-1})(x_i-x_{i+1})\cdots(x_i-x_n)}$$

[Numerator skips $(x-x_i)$; denominator skips (x_i-x_i). Proof by direct check.]

[For a variety of other curves, see *Tables*, III, pp. *19–34*.]

I. b. Solid Analytic Geometry.

[(x, y, z) denotes a point; (x_1, y_1, z_1) and (x_2, y_2, z_2) two points, etc. O denotes the origin, $(0, 0, 0)$.]

1. Distance: $P_1P_2=\sqrt{(x_2-x_1)^2+(y_2-y_1)^2+(z_2-z_1)^2}$.

2. Distance from the origin: $OP=\sqrt{x^2+y^2+z^2}$.

3. Direction cosines of a line L: $\cos\alpha$, $\cos\beta$, $\cos\gamma$, if α, β, γ denote the angles L makes with the x, y, z axes, respectively; and we have

$$\cos^2\alpha+\cos^2\beta+\cos^2\gamma=1.$$

4. Direction cosines proportional to given numbers:
If $a:b:c=\cos\alpha:\cos\beta:\cos\gamma$, and $R^2=a^2+b^2+c^2$, then

$$\cos\alpha=a/R,\ \cos\beta=b/R,\ \cos\gamma=c/R.$$

5. Angle θ between lines L and L' with direction cosines (l, m, n) and (l', m', n'):

$$\cos\theta = ll' + mm' + nn'.$$

Lines *parallel* if $ll' + mm' + nn' = 1$, or if $l = l'$, $m = m'$, $n = n'$.
Lines *perpendicular* if $ll' + mm' = nn' = 0$.

6. Direction cosines of a plane $P \equiv$ direction cosines of any line perpendicular to P.

7. Equation of a plane P:

$$lx + my + nz = p, \text{ or } x\cos\alpha + y\cos\beta + z\cos\gamma = p,$$

where (l, m, n) are the direction cosines of P, and p is the length of the perpendicular from O to P.

8. General equation of a plane: $Ax + By + Cz + D = 0$.
If $R^2 = A^2 + B^2 + C^2$, $l = \cos\alpha = A/R$, $m = B/R$, $n = C/R$, $p = -D/R$.

9. Plane with intercepts a, b, c, on the axes:

$$x/a + y/b + z/c = 1.$$

10. Plane determined by (x_1, y_1, z_1), (x_2, y_2, z_2), (x_3, y_3, z_3):

$$\begin{vmatrix} x & y & z & 1 \\ x_1 & y_1 & z_1 & 1 \\ x_2 & y_2 & z_2 & 1 \\ x_3 & y_3 & z_3 & 1 \end{vmatrix} = 0$$

11. Angle θ between two planes $(l, m, n; p)$, $(l, m, n; p)$:

$$\cos\theta = ll' + mm' + nn'.$$

12. Angle θ between planes $Ax + By + Cz + D = 0$ and $A'x + B'y + C'z + D' = 0$:

$$\cos\theta = \frac{AA' + BB' + CC'}{RR'}, \quad R^2 = A^2 + B^2 + C^2, \; R'^2 = A'^2 + B'^2 + C'^2.$$

Planes *parallel* if $ll' + mm' + nn' = 1$, or if $A = A'$, $B = B'$, $C = C'$.
Planes *perpendicular* if $AA' + BB' + CC' = 0$.

13. Distance d from point (x_1, y_1, z_1) to plane $(l, m, n; p)$:

$$d = lx_1 + my_1 + nz_1 - p.$$

14. Distance d from (x_1, y_1, z_1) to $Ax + By + Cz + D = 0$:

$$d = \frac{Ax_1 + By_1 + Cz_1 + D}{R}, \quad R^2 = A^2 + B^2 + C^2.$$

15. Direction cosines (l, m, n) of a line determined by two planes

$$Ax + By + Cz + D = 0, \quad A'x + B'y + C'z + D' = 0;$$

$$l : m : n = \begin{vmatrix} B & C \\ B' & C' \end{vmatrix} : \begin{vmatrix} C & A \\ C' & A' \end{vmatrix} : \begin{vmatrix} A & B \\ A' & B' \end{vmatrix}; \text{ see 4.}$$

16. Line through (x_1, y_1, z_1) and (x_2, y_2, z_2):

$$\frac{x - x_1}{x_2 - x_1} = \frac{y - y_1}{y_2 - y_1} = \frac{z - z_1}{z_2 - z_1}.$$

17. Line through (x_0, y_0, z_0) in direction (l, m, n):

$$\frac{x - x_0}{l} = \frac{y - y_0}{m} = \frac{z - z_0}{n}.$$

18. Line through (x_0, y_0, z_0) perpendicular to plane $Ax + By + Cz = 0$:

$$\frac{x - x_0}{A} = \frac{y - y_0}{B} = \frac{z - z_0}{C}.$$

19. Plane through (x_1, y_1, z_1) perpendicular to line of formula 17:

$$A(x - x_1) + B(y - y_1) + C(z - z_1) = 0.$$

20. Sphere of center (a, b, c) and radius r:

$$(x - a)^2 + (y - b)^2 + (z - c)^2 = r^2.$$

21. Cones with vertex at O:

$$\pm\frac{x^2}{a^2} \pm \frac{y^2}{b^2} \pm \frac{z^2}{c^2} = 0.$$

Imaginary, if all signs are alike; *otherwise real*, and sections parallel to one of the reference planes are ellipses.

22. Ellipsoids and hyperboloids with centers at O (see Tables III $N_{1, 2, 3}$).

$$\pm\frac{x^2}{a^2} \pm \frac{y^2}{b^2} \pm \frac{z^2}{c^2} = 1 \quad \left\{\begin{array}{l} \text{Signs on left:} \\ \text{All } + : \text{ ellipsoid} \\ \text{One } - : \text{ hyperboloid of one sheet} \\ \text{Two } - : \text{ hyperboloid of two sheets} \\ \text{All } - : \text{ surface imaginary} \end{array}\right.$$

23. Paraboloids on z-axis with vertices at O (see Tables III $N_{4, 5}$):

$$\pm\frac{x^2}{a^2} \pm \frac{y^2}{b^2} = cz \quad \left\{\begin{array}{l} \text{Signs on left:} \\ \text{Alike: elliptic paraboloid} \\ \text{Different: hyperbolic paraboloid} \end{array}\right.$$

24. Contour lines on curved surface $F(x, y, z) = 0$:

Sections by $z = a$ are $F(x, y, a) = 0$.

25. Curves in space:

(a) Intersection of two surfaces: $F_1(x, y, z) = 0$, $F_2(x, y, z) = 0$.

(b) Solve for y and z: $y = f(x)$, $z = \phi(x)$.

(c) Parameter forms: $x = f(t)$, $y = \phi(t)$, $z = \psi(t)$.

26. General cylinder with elements parallel to z-axis: $f(x, y) = 0$.

J. Differential Formulas.

1. $\boldsymbol{y = f(x)}$: $dy = f'(x)\,dx$, $f'(x) = dy \div dx = dy/dx$.

2. $\boldsymbol{F(x, y) = 0}$: $F_x\,dx + F_y\,dy = 0$, or $dy = -[F_x \div F_y]dx$.

3. $\boldsymbol{x = f(t),\ \ y = \phi(t)}$:

(a) $dx = f'(t)\,dt$, $dy = \phi'(t)\,dt$, $dy/dx = \phi'(t) \div f'(t)$.

(b) $d^2y/dx^2 = d[dy/dx]/dx = d[\phi' \div f']/dx = [\phi''f' - f''\phi'] \div (f')^3$.

(c) $d^3y/dx^3 = d[d^2y/dx^2]/dx = d[(\phi''f' - f''\phi') \div (f')^3]/dt \div f'$.

4. *Transformation* $\boldsymbol{x = f(t)}$: $y = \phi(x)$ becomes $y = \phi(f(t)) = \psi(t)$.

(a) dy/dx becomes $dy/dt \div f'(t)$; [see 3 (a)].

(b) d^2y/dx^2 becomes $[(d^2y/dt^2)\cdot f'(t) - (dy/dt)f''(t)] \div [f'(t)]^3$; [see 3 (b)].

5. *Transformation* $\boldsymbol{x = f(t, u),\ y = \phi(t, u)}$: $y = F(x)$ becomes $u = \Phi(t)$.

(a) dy/dx becomes $\dfrac{dy}{dt} \div \dfrac{dx}{dt}$ or $\left[\dfrac{\partial\phi}{\partial t} + \dfrac{\partial\phi}{\partial u}\cdot\dfrac{du}{dt}\right] \div \left[\dfrac{\partial f}{\partial t} + \dfrac{\partial f}{\partial u}\cdot\dfrac{du}{dt}\right]$.

(b) d^2y/dx^2 becomes $d[dy/dx]/dt \div dx/dt$; [compute as in 5 (a)].

6. *Polar Transformation* $x = \rho\cos\theta$, $y = \rho\sin\theta$.

$$dx = \cos\theta\,d\rho - \rho\sin\theta\,d\theta;\quad dy = \sin\theta\,d\rho + \rho\cos\theta\,d\theta,$$
$$d^2x = \cos\theta\,d^2\rho - 2\sin\theta\,d\rho\,d\theta - \rho\cos\theta\,d\theta^2,$$
$$d^2y = \sin\theta\,d^2\rho + 2\cos\theta\,d\rho\,d\theta - \rho\sin\theta\,d\theta^2.$$

7. $\boldsymbol{z = F(x, y)}$: $dz = F_x\,dx + F_y\,dy = p\,dx + q\,dy$; [see I, 3 (d), p. 2].

8. *Transformation* $x = f(u, v)$, $y = \phi(u, v)$: $z = F(x, y) = \Phi(u, v)$.

(a) $\dfrac{\partial z}{\partial u} = \dfrac{\partial z}{\partial x}\dfrac{\partial f}{\partial u} + \dfrac{\partial z}{\partial y}\dfrac{\partial\phi}{\partial u}$, $\quad\dfrac{\partial z}{\partial v} = \dfrac{\partial z}{\partial x}\dfrac{\partial f}{\partial v} + \dfrac{\partial z}{\partial y}\dfrac{\partial\phi}{\partial v}$.

(b) $\dfrac{\partial z}{\partial x} = A\dfrac{\partial z}{\partial u} + B\dfrac{\partial z}{\partial v}$, $\quad\dfrac{\partial z}{\partial y} = C\dfrac{\partial z}{\partial u} + D\dfrac{\partial z}{\partial v}$.

[A, B, C, D found by solving 8 (a) for $\partial z/\partial x$ and $\partial z/\partial y$.]

(c) $$\frac{\partial^2 z}{\partial x^2} = \frac{\partial}{\partial x}\left(\frac{\partial z}{\partial x}\right) = \frac{\partial}{\partial x}\left(A\frac{\partial z}{\partial u} + B\frac{\partial z}{\partial v}\right)$$
$$= A\frac{\partial}{\partial u}\left(A\frac{\partial z}{\partial u} + B\frac{\partial z}{\partial v}\right) + B\frac{\partial}{\partial v}\left(A\frac{\partial z}{\partial u} + B\frac{\partial z}{\partial v}\right).$$

[Similar expressions for $\partial^2 z/\partial y^2$ and higher derivatives.]

TABLE III

STANDARD CURVES

A. Curves $y = x^n$, all pass through (1, 1); positive powers also through (0, 0); negative powers asymptotic to the y-axis. Special cases : $n = 0, 1$

Chart of $y = x^n$ for positive, negative, fractional values of n

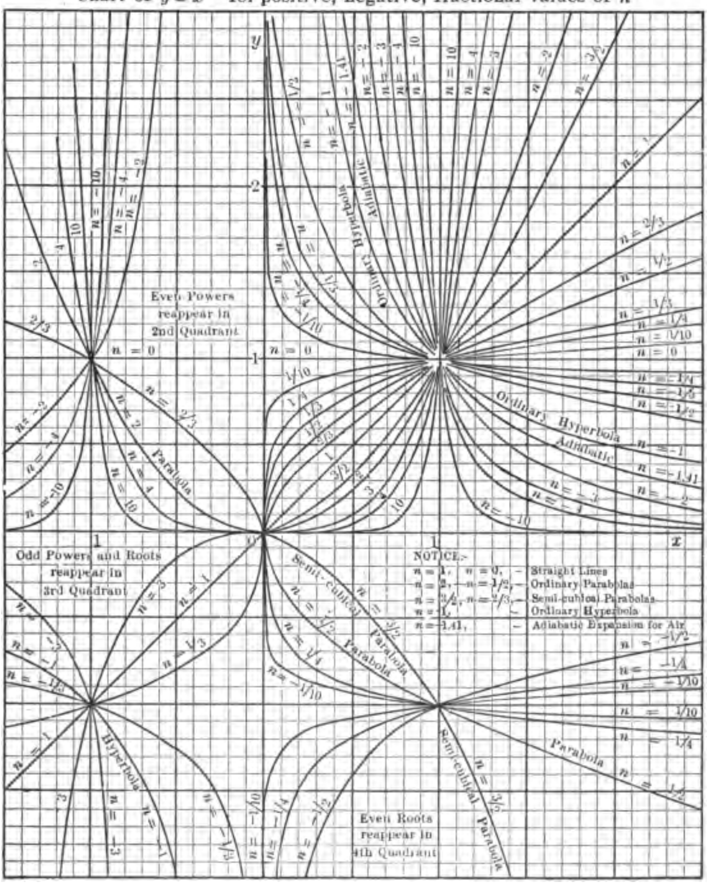

FIG. A

are **straight lines**; $n = 2$, $1/2$ are ordinary **parabolas**; $n = -1$ is an ordinary **hyperbola**; $n = 3/2$, $2/3$ are **semi-cubical parabolas**.

The curves $pv^m = c$ occur in the theory of gas expansion, where p = pressure; v = volume; c and m constants. In *isothermal* expansion (p. 105) $m = 1$, whence $pv = c$ or $p = cv^{-1}$; ($n = -1$ in Fig. A). Choose scales so that $y = p/c$ and $v = x$. In *adiabatic expansion of air*, $m = 1.41$ (nearly). The *area* $\int_{v_1}^{v_2} p\,dv$ = *work done* in compressing the gas from any given volume v_2 to a volume v_1.

B. Logarithmic Paper; Curves $y = x^n$, $y = kx^n$. Logarithmic paper is used chiefly in *experimental determination of the constants k and n*; and for *graphical tables*. In Fig. B, $k = 1$ except where given.

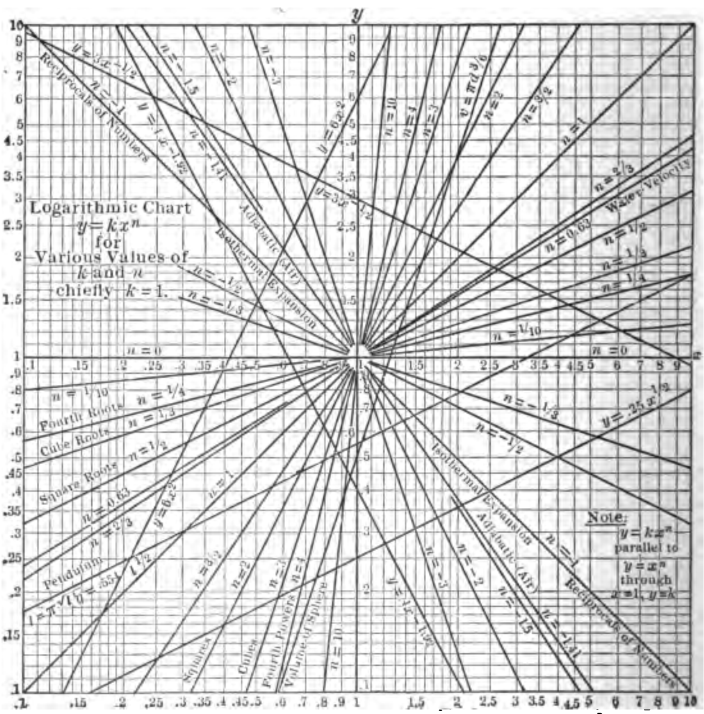

FIG. B

[See § 189, p. 284, above; also Williams-Hazen, *Hydraulic Tables;* Trautwine, *Engineers' Handbook;* D'Ocagne, *Nomographie.*] The line $y = x^{-1}$ gives the ***reciprocals of numbers*** by direct readings.

C. Trigonometric Functions. The **inverse trigonometric functions** are given by reading y first.

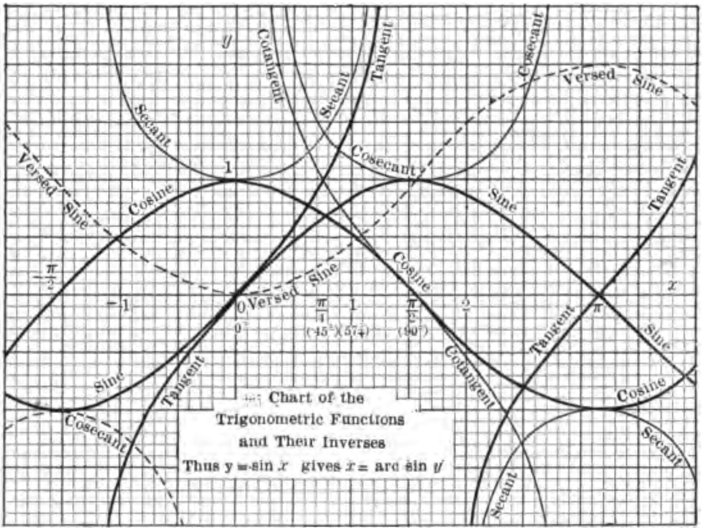

Fig. C

D. Logarithms and Exponentials: $y = \log_{10} x$ and $y = \log_e x$.
Note $\log_e x = \log_{10} x \ \log_e 10 = 2.303 \log_{10} x$. The values of the **exponential** functions $x = 10^y$ and $x = e^y$ are given by reading y first. See E.

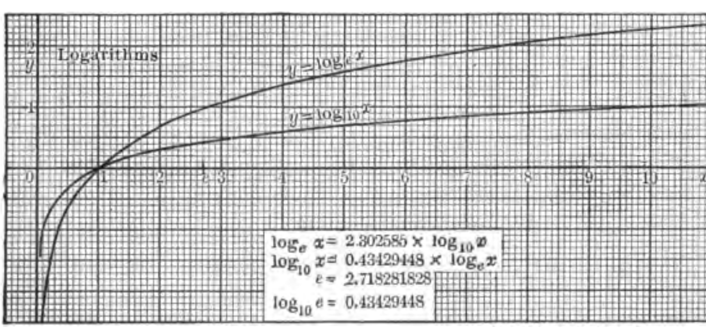

Fig. D

E. Exponential and Hyperbolic Functions. The **catenary** (hyperbolic cosine) [$y = \cosh x = (e^x + e^{-x})/2$] and the **hyperbolic sine** [$y = \sinh x = (e^x - e^{-x})/2$] are shown in their relation to the **exponential curves** $y = e^x$, $y = e^{-x}$. Notice that both hyperbolic curves are asymptotic to $y = e^x/2$.

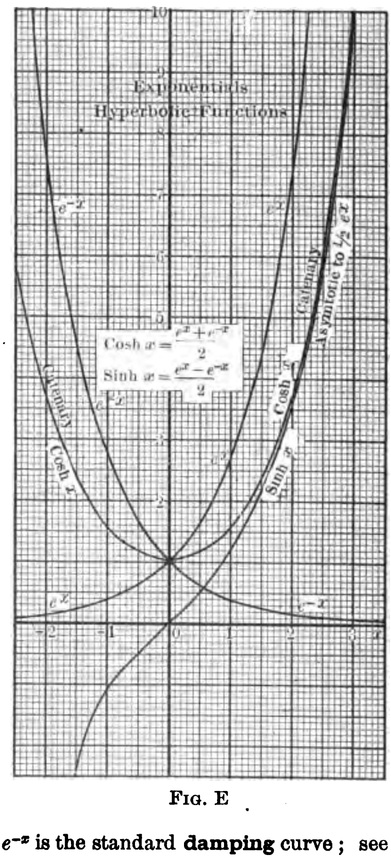

FIG. E

The curve $y = e^{-x}$ is the standard **damping** curve; see Fig. F_2, and §67, p. 108.

The **general catenary** is $y = (a/2)(e^{x/a} + e^{-x/a}) = a \cosh (x/a)$; it is the curve in which a flexible inelastic cord will hang. (Change the scale from 1 to a on both axes.)

F. Harmonic Curves. The general type of **simple harmonic curve** is $y = a \sin (kx + \epsilon)$:

CURVE	$a \sin (kx + \epsilon)$	$\sin x$	$\cos x$	$\sin 2x$	$(1/2) \sin (6x - 1.2)$
amplitude	a	1	1	1	1/2
wave-length	$2\pi/k$	2π	2π	π	$\pi/3$
phase-angle	$-\epsilon/k$	0	$\pi/2$	0	0.2

A **compound harmonic curve** is formed by superposing simple harmonics: in Fig. F_1, $y = \sin 2x + (1/2) \sin (6x - 1.2)$ is drawn.

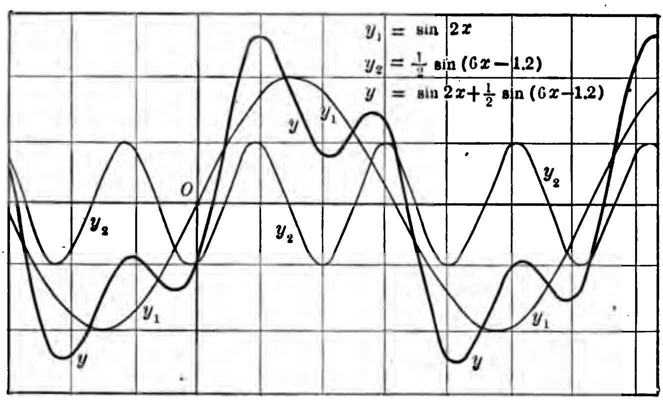

FIG. F_1

Such curves occur in theories of vibrations, sound, electricity.

The simplest type of **damped vibrations** is $y = e^{-cx} \sin kx$: Fig. F_2 shows $y = e^{-x/2} \sin 3x$. The general form is $y = ae^{-cx} \sin (kx + \epsilon)$. Such damped simple vibrations may be superposed on other damped or undamped vibrations.

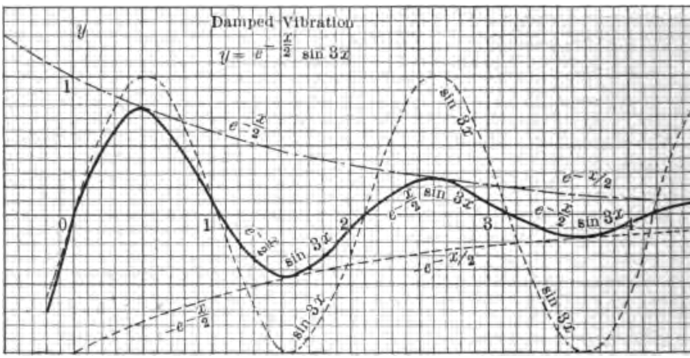

FIG. F_2

G. The Roulettes.

A roulette is the path of any point rigidly connected with a moving curve which rolls without slipping on another (fixed) curve.

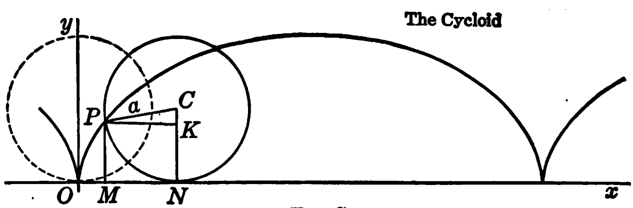

FIG. G_1

Figure G_1 shows the ordinary **cycloid**, a roulette formed by a point P on the rim of a wheel of radius a, which rolls on a straight line OX See also Fig. 36, p. 144. The equations are

$$\begin{cases} x = ON - MN = a\theta - a \sin \theta, \\ y = NC - KC = a - a \cos \theta, \end{cases}$$

where $\theta = \angle NCP$.

Figure G_2 shows the curves traced by a point on a spoke of the wheel of Fig. H, or the spoke produced. These are called **trochoids**; their equations are

$$\begin{cases} x = a\theta - b\sin\theta, \\ y = a - b\cos\theta, \end{cases}$$

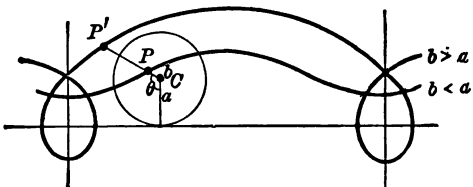

FIG. G_2 **The Trochoids**

where b is the distance PC. If $b > a$, the curve is called an **epitrochoid**; if $b < a$, a **hypotrochoid**.

Figure G_3 shows the **epicycloid**;

$$\begin{cases} x = (a+b)\cos\theta - b\cos\left[\dfrac{a+b}{b}\theta\right], \\ y = (a+b)\sin\theta - b\sin\left[\dfrac{a+b}{b}\theta\right], \end{cases}$$

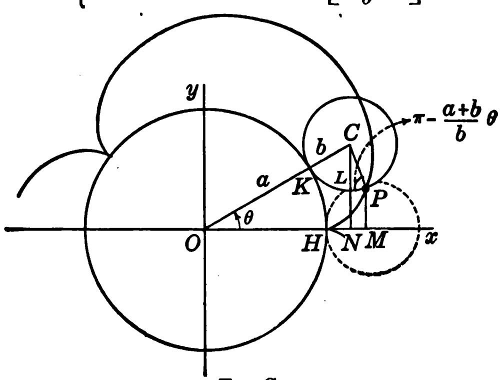

FIG. G_3

formed by a point on the circumference of a circle of radius b rolling on the exterior of a circle of radius a.

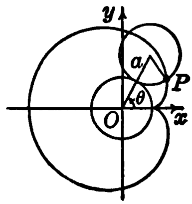

FIG. G_4

Figure G_4 shows the *special epicycloid*, $a = b$,

$$\begin{cases} x = 2\,a\cos\theta - a\cos 2\,\theta, \\ y = 2\,a\sin\theta - a\sin 2\,\theta, \end{cases}$$

which is called the **cardioid**; its equation in polar coördinates $(\rho,\ \phi)$ with pole at O' is $\rho = 2\,a\,(1 - \cos\phi)$.

Figure G_5 shows the hypocycloid:

$$\begin{cases} x = (a-b)\cos\theta + b\cos\left[\dfrac{a-b}{b}\,\theta\right], \\ y = (a-b)\sin\theta - b\sin\left[\dfrac{a-b}{b}\,\theta\right], \end{cases}$$

formed by a point on the circumference of a circle of radius b rolling on the interior of a circle of radius a.

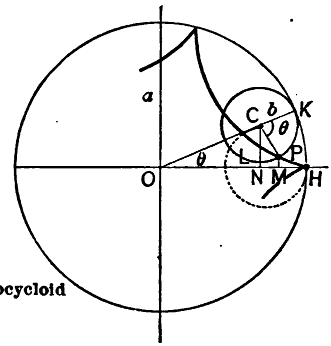

FIG. G_5

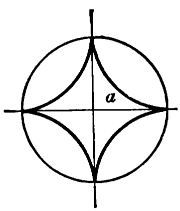

FIG. G_6

Figure G_6 shows the *special hypocycloid*, $a = 4\,b$,

$$\begin{cases} x = a\cos^3\theta, \\ y = a\sin^3\theta, \end{cases} \quad \text{or} \quad x^{2/3} + y^{2/3} = a^{2/3},$$

which is called the **four-cusped hypocycloid**, or **astroid**.

H. The Tractrix. This curve is the path of a particle P drawn by a cord PQ of fixed length a attached to a point Q which moves along the x-axis from 0 to $\pm\infty$. Its equation is

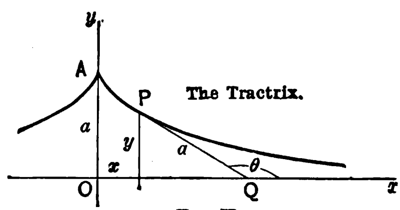

FIG. H

$$x = a\log\frac{a + \sqrt{a^2 - y^2}}{y} - \sqrt{a^2 - y^2}.$$

I. Cubic and Quartic Curves.

Figure I_1 shows the **contour lines** of the surface $z = x^3 - 3x - y^2$ cut out by the planes $z = k$, for $k = -6, -4, -2, 0, 2, 4$; that is, the **cubic curves** $x^3 - 3x - y^2 = k$.

The surface has a maximum at $x = -1$, $y = 0$; the point $x = 1$, $y = 0$ is also a critical point, but the surface cuts through its tangent plane there, along the curve $k = -2$; $y^2 = x^3 - 3x + 2$.

These curves are drawn by means of the auxiliary curve $q = x^2 - 3x$, itself a type of cubic curve; then $y = \sqrt{q - k}$ is readily computed.

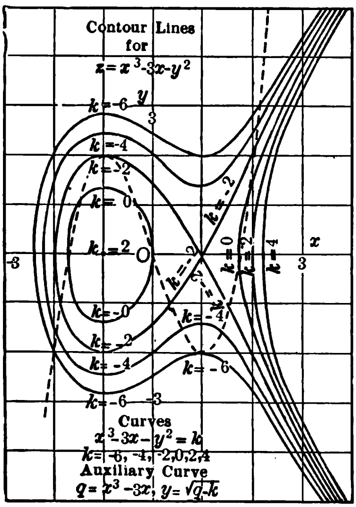

FIG. I_1

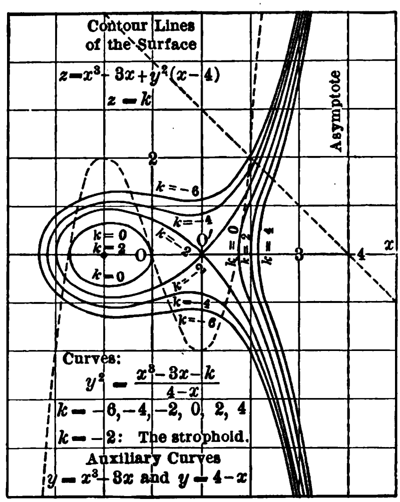

FIG. I_2

Figure I_2 shows the **contour lines** of the surface $z = x^3 - 3x + y^2(x - 4)$ for $z = k = -6, -4, -2, 0, 2, 4$; that is, the **cubic curves**

$$y^2 = (x^3 - 3x - k)/(4 - x).$$

The surface has a maximum at $(-1, 0)$. At $(1, 0)$ the horizontal tangent plane $z = -2$ cuts the surface in the **strophoid** $y^2 = (x^3 - 3x + 2)/(4 - x)$ whose equation with the new origin O' is $y^2 = x'^2(3 + x')/(3 - x')$. The line $x = 4$ is an asymptote for each of the curves.

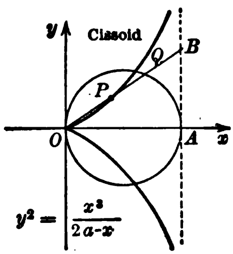

FIG. I_3

Figure I_3 shows another cubic: the **cissoid,** famous for its use in the ancient problem of the "duplication of the cube." Its equation is

$$y^2 = \frac{x^3}{2\,a - x}, \quad \text{or} \quad \rho = 2\,a \tan\theta \sin\theta.$$

It can be drawn by using an auxiliary curve as above; or by means of its geometric definition: $OP = QB$, when Oy and AB are vertical tangents to the circle OQA.

Figure I_4 shows the **conchoid** of Nicomedes, used by the ancients in the problem of trisection of an angle. Its equation is

$$y^2 = -x^2 + \left(\frac{bx}{x-a}\right)^2, \quad \text{or} \quad \rho = a \sec\theta \pm b.$$

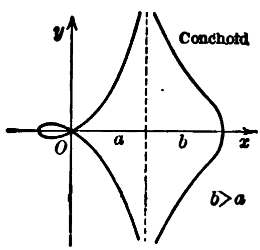

FIG. I_4

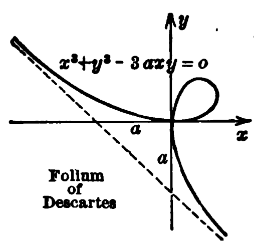

FIG. I_5

Figure I_5 shows the cubic $x^3 + y^3 - 3\,axy = 0$, called the **Folium of Descartes**; see Example, p. 45.

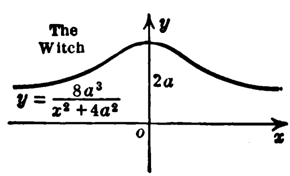

FIG. I_6

Figure I_6 shows the **witch of Agnesi**: $y = 8\,a^3/(x^2 + 4\,a^2)$; see Exs. 1, 36, p. 131; 52, p. 162; and see III, J, below.

Figure I_7 shows the **Cassinian ovals**, defined geometrically by the equation $PF \cdot PF_1 = k^2$; or by the **quartic** equation,

$$[(x-a)^2+y^2][(x+a)^2+y^2]=k^4,$$

where $a = OF$ (= 1 in Fig. I_7). The special oval $k^2 = a^2$ is called the **lemmiscate,** $(x^2+y^2)^2 = 2a^2(x^2-y^2)$ or $\rho^2 = 2a^2 \cos 2\theta$.

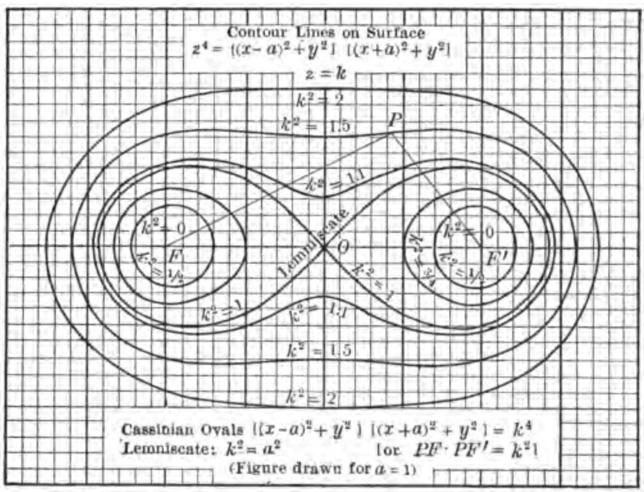

FIG. I_7

The ovals are also the *contour lines* of the surface

$$z^4=[(x-a)^2+y^2][(x+a)^2+y^2],$$

which has minima at $(x = \pm a,\ y = 0)$, and a critical point with no extreme at origin.

J. Error or Probability Curves.

Figure J_1 is the so-called **curve of error**, or probability curve

$$y = \frac{h}{\sqrt{\pi}} e^{-h^2x^2},$$

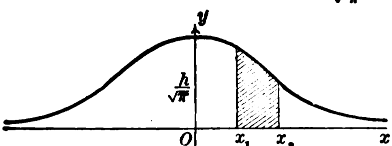

FIG. J_1

where h is the *measure of precision*. See *Tables*, IV, H, 148, p. *50*; and V, G, p. *56*.

Figure J_2 shows the very similar curve

$$y = \textbf{sech}\, x = 2/(e^x + e^{-x}).$$

In some instances this curve, or the witch (Fig. I_6), may be used in place of Fig. J_1. Any of these curves, on a proper scale, give good approximations to the probable **distribution of any accidental data** which tend to group themselves about a mean.

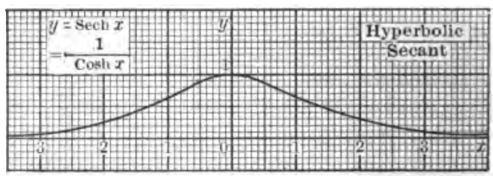

FIG. J_2

K. Polynomial Approximations.

Figure K_1 shows the first **Taylor polynomial approximations to the** function $y = \sin x$. (See § 147, p. 253.)

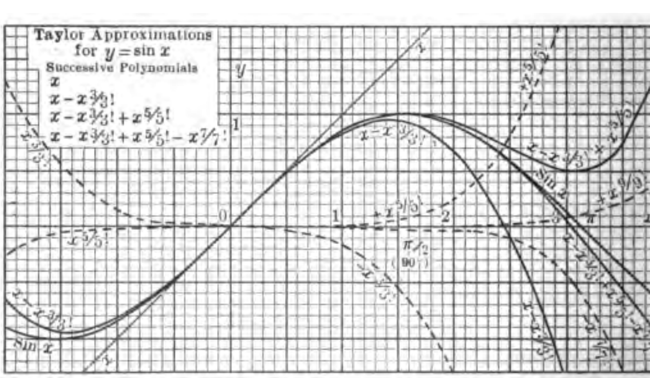

FIG. K_1

Figure K_2 shows the **Simpson-Lagrange approximations**: (1) by a broken line; (2) by an ordinary parabola; (3) by a cubic, which however degenerates into a parabola in this example. (Lagrange Interpolation Formula, *Tables*, p. *15*.)

The fourth approximation is so close that it cannot be drawn in the figure. In practice, the division points are taken closer together than is feasible in a figure.

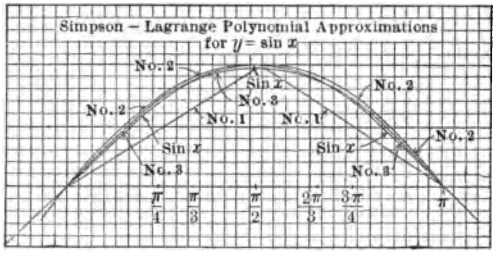

FIG. K_2

No. 1. $y = \frac{2}{\pi}x,\ 0 \leq x \leq \frac{\pi}{2};\ y = -\frac{2}{\pi}(x - \pi),\ \frac{\pi}{2} \leq x \leq \pi.$

No. 2. $y = \frac{4}{\pi}x - \frac{4}{\pi^2}x^2 = 1.273\,x - .405\,x^2,\ 0 \leq x \leq \pi.$

(Division points: $x_0 = 0,\ x_1 = \pi/2,\ x_2 = \pi.$)

No. 3. $y = \frac{9\sqrt{3}}{4\pi}x - \frac{9\sqrt{3}}{4\pi^2}x^2 - 0 \cdot x^3 = 1.245\,x - 0.395\,x^2.$

(Division points: $x_0 = 0,\ x_1 = \pi/3,\ x_2 = 2\pi/3,\ x_3 = \pi.$)

No. 4. $y = 15.38\,x - 7.642\,x^2 - 2.86\,x^3 + 0.876\,x^4.$

(Agrees too closely to show in the figure.)

L. Trigonometric Approximations.

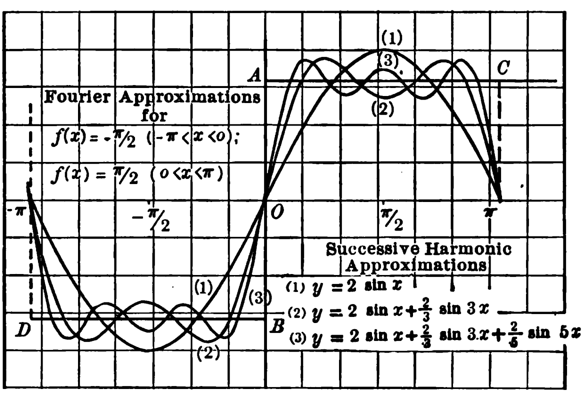

FIG. L

Figure L shows the approximation to the two detached line-segments $y = -\pi/2,\ (-\pi < x < 0),\ y = \pi/2,\ (0 < x < \pi)$ by means of an expression of the form $a_0 + a_1 \sin x + a_2 \sin 2x + \cdots + a_n \sin nx$. See II, E, 26.

TABLE IV

STANDARD INTEGRALS

Index :

A. Fundamental General Formulas.

1. If $\dfrac{du}{dx} = \dfrac{dv}{dx}$, then $u = v +$ constant. [Fundamental Theorem.]

2. If $\int u\,dx = I$, then $\dfrac{dI}{dx} = u$. [General Check.]

3. $\int cu\,dx = c\int u\,dx.$

4. $\int [u + v]\,dx = \int u\,dx + \int v\,dx.$

5. $\int u\,dv = uv - \int v\,du.$ [Parts.]

6. $\left[\int f(u)\,du\right]_{u=\phi(x)} = \int f[\phi(x)]\,\dfrac{d\phi(x)}{dx}\,dx.$ [Substitution.]

B. Integrand — Rational Algebraic.

7. $\int x^n\,dx = \dfrac{x^{n+1}}{n+1}$, $n \neq -1$, see 8.

NOTES. (a) $\int$ (Any Polynomial) dx, — use 8, 4, 7.

(b) $\int$ (Product of Two Polynomials) dx, — expand, then use 8, 4, 7.

(c) $\int c\,dx = cx$, by 8, 7.

8. $\int \dfrac{dx}{x} = \log_e x = (\log_{10} x)(\log_e 10) = (2.302585) \log_{10} x.$

NOTES. (a) $\int (1/x^m)\,dx$, — use 7 with $n = -m$ if $m \neq 1$; use 8 if $m = 1$.

(b) $\int [(\text{Any Polynomial})/x^m]\,dx$, — use short division, then 7 and 8.

9. $\int \dfrac{dx}{a^2+x^2} = \dfrac{1}{a} \arctan \dfrac{x}{a} = \dfrac{1}{a} \tan^{-1}\dfrac{x}{a} = \dfrac{1}{a} \operatorname{ctn}^{-1}\dfrac{a}{x}$

$$= -\frac{1}{a}\operatorname{ctn}^{-1}\frac{x}{a}\ [+\text{ const.}].$$

10. $\int \dfrac{dx}{x^2-a^2} = \dfrac{1}{2a} \log \dfrac{x-a}{x+a} = \dfrac{1}{2a} \log \dfrac{a-x}{a+x}$ [+ const.].

NOTE. *All rational functions are integrated by reductions to 7, 8, 9.* The reductions are performed by 3, 4, 6. No. 10 and all that follow are results of this process.

11. $\int (ax+b)^n\,dx = \dfrac{1}{a}\dfrac{(ax+b)^{n+1}}{n+1}$, $n \neq -1$. (See No. 12.) [From 7.]

12. $\int \dfrac{dx}{(ax+b)} = \dfrac{1}{a} \log (ax+b)$. [From 8.]

NOTES. (a) $\int \dfrac{Ax+B}{ax+b}\,dx$, — use long division, then 7 and 12.

(b) $\int \dfrac{\text{Any Polynomial}}{ax+b}\,dx$, — use long division, then 7 and 12.

13. $\int \dfrac{dx}{(ax+b)^m} = \dfrac{1}{a}\,\dfrac{-1}{(m-1)(ax+b)^{m-1}}$, $(m \neq 1)$. [From 11.]

14. $\int \dfrac{x\,dx}{(ax+b)^2} = \dfrac{1}{a^2}\left[\dfrac{b}{ax+b} + \log(ax+b)\right]$. [From 11, 12.]

NOTES. (a) $\int \dfrac{Ax+B}{(ax+b)^2}\,dx$, — combine A times No. 14 and B times No. 13, $m = 2$.

(b) $\int \dfrac{(\text{Any Polynomial})}{(ax+b)^2}\,dx$, — use long division, then 7 and 14 (a); or use 15

15. $\left[\int F(x, ax+b)\,dx\right]_{u=ax+b} = \frac{1}{a}\int F\left(\frac{u-b}{a}, u\right) du.$ [From 6.]

NOTES. (a) *Restatement:* put u for $ax+b$, $\frac{u-b}{a}$ for x, $\frac{du}{a}$ for dx.

(b) $\int [x/(ax+b)^3]\,dx$, — use 15. *Ans.* $\frac{1}{a^2}\left[-\frac{1}{u}+\frac{b}{2u^2}\right]_{u=a+bx}$.

(c) $\int \frac{\text{(Any Polynomial)}}{(ax+b)^3}dx$, — use 15; then 8 (b).

(d) $\int \frac{\text{(Any Polynomial)}}{(ax+b)^m}dx$, — use 15 unless $m<3$, ; but see 12 (b), 14 (b).

(e) $\int x^n(ax+b)^m\,dx$, — use 15 if $m>n$; use 7 (b) if $m \leqq n$; see also 51–54.

16. $$\frac{1}{(ax+b)(cx+d)} = \frac{1}{ad-bc}\left[\frac{a}{ax+b} - \frac{c}{cx+d}\right].$$

NOTES. (a) $\int \frac{dx}{(ax+b)(cx+d)}$, — use 16, then 12. Special cases, — see 10 and 16 (b).

(b) $\int \frac{dx}{x(ax+b)} = \frac{1}{b}\int\left[\frac{1}{x} - \frac{a}{ax+b}\right]dx.$ (Special case of 16 (a).)

(c) $\int \frac{Ax+B}{(ax+b)(cx+d)}dx$, — use 16, then long division, 12.

(d) $\int \frac{\text{(Any Polynomial)}}{(ax+b)(cx+d)}dx$, — use 16, then long division, 7, 12.

(e) If $ad-bc=0$, 18 can be used.

17. $$\left[\int F(x, ax+b)\,dx\right]_{u=\frac{ax+b}{x}} = \int F\left(\frac{b}{u-a}, \frac{bu}{u-a}\right)\cdot\frac{-b\,du}{(u-a)^2}.$$

NOTES. (a) *Restatement:*

Put u for $\frac{ax+b}{x}$; $\frac{b}{u-a}$ for x; $\frac{bu}{u-a}$ for $ax+b$; $\frac{-b\,du}{(u-a)^2}$ for dx.

(b) $\int \frac{dx}{x^n(ax+b)^m} = -\frac{1}{b^{m+n-1}}\int\frac{(u-a)^{m+n-2}}{u^m}du$; then use 8 b.

(c) $\int \frac{dx}{x^2(ax+b)} = -\frac{u-a\log u}{b^2}$. (d) $\int \frac{dx}{x^3(ax+b)} = -\frac{u^2-4au+2a^2\log u}{2b^3}$.

18. $$\int \frac{dx}{ax^2+b} = \frac{1}{\sqrt{ab}}\tan^{-1} x\sqrt{\frac{a}{b}}, \text{ if } a>0,\ b>0. \quad \text{[See 9.]}$$

$$= \frac{1}{2\sqrt{-ab}}\log\frac{\sqrt{a}\,x-\sqrt{-b}}{\sqrt{a}\,x+\sqrt{-b}}, \text{ if } a>0,\ b<0. \quad \text{[See 10.]}$$

NOTES. (a) $\int \frac{dx}{ax^2-c}$, — use 18 (2nd part); $b=-c$. (b) $\int \frac{dx}{c-ax^2} = -\int\frac{dx}{ax^2-c}$.

19. $\int \frac{x\,dx}{ax^2+b} = \frac{1}{2a}\log(ax^2+b).$

NOTES. (*a*) $\int \frac{x^2\,dx}{ax^2+b}$, — use long division, then 18.

(*b*) $\int \frac{Ax+B}{ax^2+b}\,dx$, — use 18, 19.

(*c*) $\int \frac{\text{(Any Polynomial)}}{ax^2+b}\,dx$, — use long division, then 18, 19.

20. $\frac{1}{(mx+n)(ax^2+b)} = \frac{1}{an^2+bm^2}\left[\frac{m^2}{mx+n} - a\frac{mx-n}{ax^2+b}\right].$

NOTES. (*a*) $\int \frac{1}{(mx+n)(ax^2+b)}\,dx$, — use 20, then 12, 18, 19.

(*b*) $\frac{Ax^2+Bx+C}{(mx+n)(ax^2+b)} = \frac{A}{a}\frac{1}{mx+n} + \frac{B}{m}\frac{1}{ax^2+b} + \left(C - \frac{Ab}{a} - \frac{Bn}{m}\right)\frac{1}{(mx+n)(ax^2+b)}.$

(*c*) $\int \frac{\text{Any Polynomial}}{(mx+n)(ax^2+b)}\,dx$, — use long division, then 20 *b*, 12, 18, 20 *a*.

21. $ax^2+bx+c = a\left[x+\frac{b}{2a}\right]^2 - \frac{b^2-4ac}{4a}.$

NOTES. (*a*) $\int \left[\frac{dx}{ax^2+bx+c}\right]_{u=x+\frac{b}{2a}} = \int \frac{du}{au^2 - \frac{b^2-4ac}{4a}}$, then 18.

(*b*) $\left[\int F(x,\ ax^2+bx+c)\,dx\right]_{u=x+\frac{b}{2a}} = \int F\left(u-\frac{b}{2a},\ au^2 - \frac{b^2-4ac}{4a}\right)du.$

(*c*) $\int \frac{\text{Any Polynomial}}{ax^2+bx+c}\,dx$, — long division, then 7, 21, 21 *b*, 18, and 19.

(*d*) $\int \frac{\text{Any Polynomial}}{\text{Any Cubic}}\,dx$, — long division, then find one real factor of cubic, then use 21, 21 *b*. [If the cubic has a double factor, set $u =$ that factor, then use 17 *c*.]

22. $\int \frac{x\,dx}{(ax^2+b)^2} = -\frac{1}{2a}\frac{1}{ax^2+b}.$

23. $\int \frac{dx}{(ax^2+b)^2} = \frac{x}{2b(ax^2+b)} + \frac{1}{2b}\int \frac{dx}{ax^2+b}$; then 18.

24. $\int \frac{x\,dx}{(ax^2+b)^m} = \left[\frac{1}{2a}\int \frac{du}{u^m}\right]_{u=ax^2+b}$; then 7 or 8.

25. $\int \frac{dx}{(ax^2+b)^m} = \frac{1}{2b(m-1)}\frac{x}{(ax^2+b)^{m-1}} + \frac{2m-3}{2(m-1)b}\int \frac{dx}{(ax^2+b)^{m-1}}$

NOTES. (*a*) Use 25 repeatedly to reach 23 and thence 18.

(*b*) Final forms in **partial fraction** reduction are of types 12, 24, 25 (by use of 21)

C. (a) Integrand Irrational: involving $r = \sqrt{ax+b}$.

26. $\left[\int F(x, \sqrt{ax+b})\,dx\right]_{r=\sqrt{ax+b}} = \int F\left(\frac{r^2-b}{a}, r\right)\frac{2r}{a}\,dr.$

27. $\int \sqrt{ax+b}\,dx = \int r\,\frac{2r}{a}\,dr = \frac{2}{3a}r^3,\ r = \sqrt{ax+b}.$

28. $\int x\sqrt{ax+b}\,dx = \frac{2}{a^2}\int (r^4 - br^2)\,dr = \frac{2r^3}{a^2}\left[\frac{r^2}{5} - \frac{b}{3}\right].$

29. $\int \frac{dx}{\sqrt{ax+b}} = \frac{2}{a}\int dr = \frac{2}{a}r.$

30. $\int \frac{dx}{x\sqrt{ax+b}} = \int \frac{2\,dr}{r^2-b}$; use 9 or 10.

31. $\int \frac{dx}{x^2\sqrt{ax+b}} = 2a\int \frac{dr}{(r^2-b)^2}$; use 23.

NOTE. $\sqrt{ax+b} = (ax+b)/\sqrt{ax+b}$; $(\sqrt{ax+b})^3 = (ax+b)\sqrt{ax+b}$.

(b) Integrand Irrational: involving $\sqrt{\pm x^2 \pm a^2}$.

32. $\int \frac{dx}{\sqrt{a^2-x^2}} = \text{arc sin}\,\frac{x}{a} = \sin^{-1}\frac{x}{a} = -\cos^{-1}\frac{x}{a} + [\text{const.}].$

33. $\int \frac{dx}{\sqrt{x^2 \pm a^2}} = \log(x + \sqrt{x^2 \pm a^2}) = \sinh^{-1}\frac{x}{a}\ [+\text{const.}]$ for $+$,

or $\cosh^{-1}\frac{x}{a}\ [+\text{const.}]$ for $-$.

34. $\int \frac{dx}{\sqrt{2ax - x^2}} = \sin^{-1}\left(\frac{x-a}{a}\right) = -\cos^{-1}\frac{x-a}{a}\ [+\text{const.}]$

$= \text{vers}^{-1}(x/a) + \text{const.}$

35. $\int \frac{dx}{x\sqrt{x^2-a^2}} = \frac{1}{a}\sec^{-1}\frac{x}{a} = \frac{1}{a}\cos^{-1}\frac{a}{x} = -\frac{1}{a}\csc^{-1}\frac{x}{a}\,[+\text{const.}].$

36. $\int \frac{x\,dx}{\sqrt{a^2-x^2}} = -\sqrt{a^2-x^2}.$ 38. $\int x\sqrt{a^2-x^2}\,dx = \frac{-1}{3}(\sqrt{a^2-x^2})^3.$

37. $\int \frac{x\,dx}{\sqrt{x^2 \pm a^2}} = \sqrt{x^2 \pm a^2}.$ 39. $\int x\sqrt{x^2+a^2}\,dx = \frac{1}{3}(\sqrt{x^2+a^2})^3.$

NOTES. (a) 32 and 33 furnish the basis for all which follow.
(b) 36, 37, 38, 39 follow from $x\,dx = d(x^2 + \text{const.})/2$.

40. $\int \frac{x^2dx}{\sqrt{a^2-x^2}} = -\frac{x}{2}\sqrt{a^2-x^2} + \frac{a^2}{2}\sin^{-1}\frac{x}{a}.$

41. $\int \frac{dx}{x\sqrt{a^2 \pm x^2}} = -\frac{1}{a}\log\left[\frac{a+\sqrt{a^2 \pm x^2}}{x}\right].$

42. $\int \frac{dx}{x^2\sqrt{a^2-x^2}} = -\frac{1}{a^2x}\sqrt{a^2-x^2}.$

43. (a) $\int \sqrt{a^2-x^2}\,dx = \frac{x}{2}\sqrt{a^2-x^2} + \frac{a^2}{2}\sin^{-1}\frac{x}{a}.$

(b) $\int \frac{\sqrt{a^2-x^2}}{x}dx = \sqrt{a^2-x^2} - a\log\frac{a+\sqrt{a^2-x^2}}{x}.$

(c) $\int \frac{\sqrt{a^2-x^2}}{x^2}dx = -\frac{\sqrt{a^2-x^2}}{x} - \sin^{-1}\frac{x}{a}.$

44. $\int \frac{x^2dx}{\sqrt{x^2 \pm a^2}} = \frac{x}{2}\sqrt{x^2 \pm a^2} \mp \frac{a^2}{2}\log(x+\sqrt{x^2 \pm a^2}).$

45. $\int \frac{dx}{x^2\sqrt{x^2 \pm a^2}} = \mp\frac{\sqrt{x^2 \pm a^2}}{a^2x}.$

46. (a) $\int \sqrt{x^2 \pm a^2}\,dx = \frac{x}{2}\sqrt{x^2 \pm a^2} \pm \frac{a^2}{2}\log(x+\sqrt{x^2 \pm a^2}).$

(b) $\int \frac{\sqrt{x^2 \pm a^2}}{x}dx = \sqrt{x^2 \pm a^2} \pm a^2\int \frac{dx}{x\sqrt{x^2 \pm a^2}}$, **then 35 or 41.**

(c) $\int \frac{\sqrt{x^2 \pm a^2}}{x^2}dx = -\frac{\sqrt{x^2 \pm a^2}}{x} + \int \frac{dx}{\sqrt{x^2 \pm a^2}}$, **then 32 or 33.**

47. $\int \frac{dx}{(\sqrt{a^2-x^2})^3} = \frac{x}{a^2\sqrt{a^2-x^2}}.$ 48. $\int \frac{dx}{(\sqrt{x^2 \pm a^2})^3} = \frac{\pm x}{a^2\sqrt{x^2 \pm a^2}}.$

Notes. ***Trigonometric Substitutions.*** **If the desired form is not found in 32–48, try 79. Then use Nos. 55–79, see 79. (*b*) See also D 51–54, below.**

49. $\sqrt{\pm(ax^2+bx+c)} = \sqrt{a}\,\sqrt{\pm u^2 \pm k^2}$, **where**

$u = x + \frac{b}{2a}$ **and** $k^2 = \frac{b^2-4ac}{4a^2}.$

50. $\sqrt{\dfrac{ax+b}{cx+d}} = \dfrac{ax+b}{\sqrt{(ax+b)(cx+d)}} = \dfrac{\sqrt{(ax+b)(cx+d)}}{cx+d}$.

NOTES. (*a*) Integrals containing $\sqrt{(ax+b)/(cx+d)}$: use 50, then 49, then 32–48.
(*b*) Substitution of $u = \sqrt{(ax+b)/(cx+d)}$ is successful without 50.

D. Integrals of Binomial Differentials — Reduction Formulas.

Symbols: $u = ax^n + b$; a, b, p, m, n, any numbers for which no denominator in the formula vanishes.

51. $\int x^m(ax^n+b)^p\,dx = \dfrac{1}{m+np+1}\left[x^{m+1}u^p + npb\int x^m u^{p-1}\,dx\right]$.

52. $\int x^m(ax^n+b)^p\,dx$
$= \dfrac{1}{bn(p+1)}\left[-x^{m+1}u^{p+1} + (m+n+np+1)\int x^m u^{p+1}\,dx\right]$.

53. $\int x^m(ax^n+b)^p\,dx$
$= \dfrac{1}{(m+1)b}\left[x^{m+1}u^{p+1} - a(m+n+np+1)\int x^{m+n}u^p\,dx\right]$.

54. $\int x^m(ax^n+b)^p\,dx$
$= \dfrac{1}{a(m+np+1)}\left[x^{m-n+1}u^{p+1} - (m-n+1)b\int x^{m-n}u^p\,dx\right]$.

NOTES. (*a*) These **reduction formulas** useful when p, m, or n are **fractional**; hence applications to **Irrational Integrands**.
(*b*) Repeated application may reduce to one of 32–48.
(*c*) Do not apply if p, m, n, are all integral, unless $n \geq 2$ and p large. Note 11, 15, 17–25.

E_a. Integrand Transcendental: Trigonometric Functions.

55. $\int \sin x\,dx = -\cos x$.

56. $\int \sin^2 x\,dx = -\frac{1}{2}\cos x \sin x + \frac{1}{2}x = -\frac{1}{4}\sin 2x + \frac{1}{2}x$.

NOTE. $\int \sin^2 kx\,dx$, — set $kx = u$, and use 56. Likewise in 55–78.

57. $\int \sin^n x\,dx = -\dfrac{\sin^{n-1}x\cos x}{n} + \dfrac{n-1}{n}\int \sin^{n-2}x\,dx$.

NOTE. If n is odd, put $\sin^2 x = 1 - \cos^2 x$ and use 62.

58. $\int \cos x\,dx = \sin x.$

59. $\int \cos^2 x\,dx = \frac{1}{2}\sin x\cos x + \frac{1}{2}x = \frac{1}{4}\sin 2x + \frac{1}{2}x.$

60. $\int \cos^n x\,dx = \frac{\cos^{n-1}x\sin x}{n} + \frac{n-1}{n}\int \cos^{n-2}x\,dx.$

NOTE. If n is odd, put $\cos^2 x = 1 - \sin^2 x$ and use 63.

61. $\int \sin x\cos x\,dx = -\frac{1}{4}\cos 2x = \frac{1}{2}\sin^2 x\,[+\text{ const.}].$

62. $\int \sin x\cos^n x\,dx = -\frac{\cos^{n+1}x}{n+1},\ n \neq -1.$

63. $\int \sin^n x\cos x\,dx = \frac{\sin^{n+1}x}{n+1},\ n \neq -1.$

64. $$\int \sin^n x\cos^m x\,dx = \frac{\sin^{n+1}x\cos^{m-1}x}{m+n} + \frac{m-1}{m+n}\int \sin^n x\cos^{m-2}x\,dx$$
$$= \frac{-\sin^{n-1}x\cos^{m+1}x}{m+n} + \frac{n-1}{m+n}\int \sin^{n-2}x\cos^m x\,dx.$$

NOTE. If n is an odd integer, set $\sin^2 x = 1 - \cos^2 x$ and use 62. If m is odd, use 63.

65. $\int \sin(mx)\cos(nx)\,dx = -\frac{\cos[(m+n)x]}{2(m+n)} - \frac{\cos[(m-n)x]}{2(m-n)},$
$m \neq \pm n.$

66. $\int \sin(mx)\sin(nx)\,dx = \frac{\sin[(m-n)x]}{2(m-n)} - \frac{\sin[(m+n)x]}{2(m+n)},\ m \neq \pm n.$

67. $\int \cos(mx)\cos(nx)\,dx = \frac{\sin[(m-n)x]}{2(m-n)} + \frac{\sin[(m+n)x]}{2(m+n)},\ m \neq \pm n.$

68. $\int \tan x\,dx = -\log\cos x.$ 69. $\int \tan^2 x\,dx = \tan x - x.$

70. $\int \tan^n x\,dx = \frac{\tan^{n-1}x}{n-1} - \int \tan^{n-2}x\,dx.$

71. $\int \operatorname{ctn} x\,dx = \log\sin x.$ 72. $\int \operatorname{ctn}^2 x\,dx = -\operatorname{ctn} x - x.$

73. $\int \operatorname{ctn}^n x\,dx = -\frac{\operatorname{ctn}^{n-1}x}{n-1} - \int \operatorname{ctn}^{n-2}x\,dx.$

74. $\int \sec x\,dx = \log\tan\left(\frac{x}{2}+\frac{\pi}{4}\right) = \log(\sec x + \tan x)\,[+\text{ const.}].$

75. $\int \csc x\,dx = \log \tan \frac{x}{2} = -\log(\csc x + \operatorname{ctn} x)\,[+\text{const.}].$

76. $\int \sec^2 x\,dx = \tan x.$ 77. $\int \csc^2 x\,dx = -\operatorname{ctn} x.$

78. $\int \sec^m x \csc^n x\,dx = \int \frac{dx}{\sin^n x \cos^m x}$ (See also 64.)

$$= \frac{1}{m-1}\sec^{m-1} x \csc^{n-1} x + \frac{m+n-2}{m-1}\int \sec^{m-2} x \csc^n x\,dx$$

$$= -\frac{1}{n-1}\sec^{m-1} x \csc^{n-1} x + \frac{m+n-2}{n-1}\int \sec^m x \csc^{n-2} x\,dx.$$

NOTES. (*a*) In 64 and 78 and many others, m and n may have negative values.

(*b*) To reduce $\int [\sin^n x/\cos^m x]\,dx$ take m negative in 64.

(*c*) To reduce $\int [\cos^m x/\sin^n x]\,dx$ take n negative in 64.

79. **Substitutions**:

	$u =$	du	$\sin x$	$\cos x$	$\tan x$	x	dx
(1)	$\sin x$	$\cos x\,dx$	u	$\sqrt{1-u^2}$	$\frac{u}{\sqrt{1-u^2}}$	$\sin^{-1} u$	$\frac{du}{\sqrt{1-u^2}}$
(2)	$\cos x$	$-\sin x\,dx$	$\sqrt{1-u^2}$	u	$\frac{\sqrt{1-u^2}}{u}$	$\cos^{-1} u$	$-\frac{du}{\sqrt{1-u^2}}$
(3)	$\tan x$	$\sec^2 x\,dx$	$\frac{u}{\sqrt{1+u^2}}$	$\frac{1}{\sqrt{1+u^2}}$	u	$\tan^{-1} u$	$\frac{du}{1+u^2}$
(4)	$\sec x$	$\sec x \tan x\,dx$	$\frac{\sqrt{u^2-1}}{u}$	$\frac{1}{u}$	$\sqrt{u^2-1}$	$\sec^{-1} u$	$\frac{du}{u\sqrt{u^2-1}}$
(5)	$\tan\frac{x}{2}$	$\frac{1}{2}\sec^2\frac{x}{2}\,dx$	$\frac{2u}{1+u^2}$	$\frac{1-u^2}{1+u^2}$	$\frac{2u}{1-u^2}$	$2\tan^{-1} u$	$\frac{2\,du}{1+u^2}$

Replace $\operatorname{ctn} x$, $\sec x$, $\csc x$ by $1/\tan x$, $1/\cos x$, $1/\sin x$, respectively.

NOTES. (*a*) $\int F(\sin x)\cos x\,dx$, — use 79, (1).

(*b*) $\int F(\cos x)\sin x\,dx$, — use 79, (2).

(*c*) $\int F(\tan x)\sec^2 x\,dx$, — use 79, (3).

(*d*) **Inspection** of this table shows *desirable substitutions* from trigonometric to algebraic, and conversely. Thus, if only $\tan x$, $\sin^2 x$, $\cos^2 x$ appear, use 79, (3).

80. $$\int\frac{dx}{a+b\sin x}=\frac{1}{\sqrt{a^2-b^2}}\sin^{-1}\frac{b+a\sin x}{a+b\sin x},\ \text{if } a^2>b^2;$$
$$=\frac{1}{\sqrt{b^2-a^2}}\log\frac{b-\sqrt{b^2-a^2}+a\tan(x/2)}{b+\sqrt{b^2-a^2}+a\tan(x/2)},\ \text{if } a^2<b^2.$$

81. $$\int\frac{dx}{a+b\cos x}=\frac{2}{\sqrt{a^2-b^2}}\tan^{-1}\left[\sqrt{\frac{a-b}{a+b}}\tan\frac{x}{2}\right],\ a^2>b^2;$$
$$=\frac{1}{\sqrt{b^2-a^2}}\log\frac{\sqrt{b+a}+\sqrt{b-a}\tan(x/2)}{\sqrt{b+a}-\sqrt{b-a}\tan(x/2)},\ a^2<b^2.$$

82. $$\int\frac{dx}{a\sin x+b\cos x}=\frac{1}{\sqrt{a^2+b^2}}\log\tan\frac{x+\alpha}{2},\ \alpha=\sin^{-1}\frac{b}{\sqrt{a^2+b^2}}.$$

NOTES. (*a*) $\int\frac{\cos x\,dx}{a+b\sin x}$, — use 79, (1), $=\frac{1}{b}\log(a+b\sin x)$.

(*b*) $\int\frac{A+B\sin x+C\cos x}{a+b\sin x}dx=C\int\frac{\cos x\,dx}{a+b\sin x}+\frac{B}{b}\int dx+\frac{Ab-Ba}{b}\int\frac{dx}{a+b\sin x}$, then use 82 *a*, 80.

(*c*) Many others similar to (*a*) and (*b*); *e.g.* $\int[\sin x/(a+b\cos x)]\,dx$, — use 79, (2).

(*d*) $\int\frac{dx}{a^2\sin^2 x+b^2\cos^2 x}$ and like forms, — use 79, (8); see 79, note *d*.

(*e*) As **last resort**, use 79, (5), for any rational trigonometric integral.

E_b. Integrand Transcendental: Trigonometric-Algebraic.

83. $$\int x^m\sin x\,dx=-x^m\cos x+m\int x^{m-1}\cos x\,dx.$$

84. $$\int x^m\cos x\,dx=x^m\sin x-m\int x^{m-1}\sin x\,dx.$$

NOTES. (*a*) $\int x\sin x\,dx=-x\cos x+\int\cos x\,dx$, — use 58.

(*b*) $\int x^m\sin x\,dx$, — repeat 83 to reach 58.

(*c*) $\int$ (Any Polynomial) $\sin x\,dx$, — split up and use 83.

(*d*) For $\cos x$ repeat (*a*), (*b*), (*c*).

85. $$\int\frac{\sin x\,dx}{x^m}=\frac{-\sin x}{(m-1)x^{m-1}}+\frac{1}{m-1}\int\frac{\cos x}{x^{m-1}}dx,\ m\neq 1.$$

86. $$\int\frac{\cos x\,dx}{x^m}=-\frac{\cos x}{(m-1)x^{m-1}}-\frac{1}{m-1}\int\frac{\sin x}{x^{m-1}}dx,\ m\neq 1.$$

87. $\int \frac{\sin x}{x}\,dx = \int \left[1 - \frac{x^2}{3!} + \frac{x^4}{5!} - \cdots\right] dx$; see II, E, 13, p. *8*.

88. $\int \frac{\cos x}{x}\,dx = \int \left[\frac{1}{x} - \frac{x}{2!} + \frac{x^3}{4!} - \cdots\right] dx$; see II, E, 14, p. *8*.

Note. Other trigonometric-algebraic combinations, use 5; or 79 followed by 89–94.

E_c. Integrand Transcendental: Inverse Trigonometric.

89. $\int \sin^{-1} x\,dx = x \sin^{-1} x + \sqrt{1 - x^2}$. [From 5.]

90. $\int \cos^{-1} x\,dx = x \cos^{-1} x - \sqrt{1 - x^2}$.

91. $\int \tan^{-1} x\,dx = x \tan^{-1} x - \frac{1}{2} \log(1 + x^2)$.

92. $\int x^n \sin^{-1} x\,dx = \frac{x^{n+1} \sin^{-1} x}{n+1} - \frac{1}{n+1} \int \frac{x^{n+1}\,dx}{\sqrt{1-x^2}}$, then 53 or 54, 32, 36.

93. $\int x^n \cos^{-1} x\,dx = \frac{x^{n+1} \cos^{-1} x}{n+1} + \frac{1}{n+1} \int \frac{x^{n+1}\,dx}{\sqrt{1-x^2}}$, then 53 or 54, 32, 36.

94. $\int x^n \tan^{-1} x\,dx = \frac{x^{n+1} \tan^{-1} x}{n+1} - \frac{1}{n+1} \int \frac{x^{n+1}\,dx}{1+x^2}$, then 19 (*c*).

Notes. (*a*) Replace $\operatorname{ctn}^{-1} x$ by $\frac{\pi}{2} - \tan^{-1} x$; or by $\tan^{-1}(1/x)$ and substitute $1/x = u$.
(*b*) Replace $\sec^{-1} x$ by $\cos^{-1}(1/x)$, $\csc^{-1} x$ by $\sin^{-1}(1/x)$ and substitute $1/x = u$.
(*c*) $\int$ (Any Polynomial) $\sin^{-1} x\,dx$, split up and use 92. (Similarly for $\cos^{-1} x$, etc.)
(*d*) $\int f(x) \sin^{-1} x\,dx$, – use (5) with $u = \sin^{-1} x$. (Similarly for $\cos^{-1} x$ and $\tan^{-1} x$.)
(*e*) Other Inverse Trigonometric Integrands, use 79 or 5.

E_d. Integrand Transcendental: Exponential and Logarithmic

95. $\int a^x dx = \frac{a^x}{\log_e a} = \frac{a^x}{\log_{10} a} \log_{10} e = \frac{a^x}{\log_{10} a} 0.4343.$

96. $\int e^x\,dx = e^x.$

Notes. (*a*) $\int e^{kx} dx = e^{kx} \div k$. (*b*) Notice $a^x = e^{(\log_e a)x} = e^{kx}$, $k = \log_e a$.

97. $\int x^n e^{kx}\,dx = \frac{1}{k} x^n e^{kx} - \frac{n}{k} \int x^{n-1} e^{kx}\,dx.$

Notes. (*a*) $\int x e^{kx} dx = x e^{kx}/k - e^{kx}/k^2$. (*b*) $\int x^n e^{kx} dx$, — repeat 97 to reach 97 (*a*)
(*c*) $\int$ (Any Polynomial) $e^{kx} dx$, split up and use 97.

98. $\int \frac{e^{kx}}{x^m}\,dx = -\frac{e^{kx}}{(m-1)\,x^{m-1}} + \frac{k}{m-1}\int \frac{e^{kx}}{x^{m-1}}\,dx$ (repeat to reach 99).

99. $\int \frac{e^{kx}}{x}\,dx = \int \left[\frac{1}{u} + 1 + \frac{u}{2!} + \frac{u^2}{3!} + \cdots\right] du,\ u = kx$; see *Tables*, V, H

100. $\int e^{kx} \sin nx\,dx = e^{kx}\frac{k \sin nx - n \cos nx}{k^2 + n^2}.$

101. $\int e^{kx} \cos mx\,dx = e^{kx}\frac{k \cos mx + m \sin mx}{k^2 + m^2}.$

102. $\int \log x\,dx = x \log x - x.$

103. $\int (\log x)^n \frac{dx}{x} = \frac{(\log x)^{n+1}}{n+1},\ n \neq -1.$

104. $\int \frac{dx}{\log x} = \int \frac{e^u\,du}{u},\ u = \log x$; see 99 and *Tables*, V, H.

105. $\int x^n \log x\,dx = x^{n+1}\left[\frac{\log x}{n+1} - \frac{1}{(n+1)^2}\right].$

106. $\int e^{kx} \log x\,dx = \frac{1}{k} e^{kx} \log x - \frac{1}{k}\int \frac{e^{kx}}{x}\,dx$, see 99.

F. Some Important Definite Integrals.

107. $\int_1^\infty \frac{dx}{x^m} = \frac{1}{m-1}$; **if $m > 1$** (otherwise non-existent).

108. $\int_0^\infty \frac{dx}{a^2 + b^2x^2} = \frac{\pi}{2\,ab}.$

109. $\int_0^\infty x^n e^{-x}\,dx = \Gamma(n+1) = n!$ if n is integral. See V, F, p. *56*.

NOTES. (*a*) In general, $\Gamma(n+1) = n \cdot \Gamma(n)$, as for $n!$, if $n > 0$.
(*b*) $\Gamma(2) = \Gamma(1) = 1$, $\Gamma(1/2) = \sqrt{\pi}$. $\Gamma(n+1) = \Pi(n)$.

110. $\int_0^1 x^m(1-x)^n\,dx = \frac{\Gamma(m+1)\,\Gamma(n+1)}{\Gamma(m+n+2)}.$

111. $\int_0^\pi \sin nx \cdot \sin mx\,dx = \int_0^\pi \cos nx \cos mx\,dx = 0$, **if $m \neq n$**, if m and n are integral.

112. $\int_0^\pi \sin^2 nx\,dx = \int_0^\pi \cos^2 nx\,dx = \pi/2$; n integral, see 56, 59.

113. $\int_0^\infty e^{-kx}\,dx = 1/k.$ 114. $\int_0^\infty [(\sin nx)/x]\,dx = \pi/2.$

115. $\int_0^\infty e^{-kx}\sin nx\,dx = n/(k^2+n^2)$, if $k>0$.

116. $\int_0^\infty e^{-kx}\cos mx\,dx = k/(k^2+m^2)$, if $k>0$.

117. $\int_0^\infty e^{-kx}x^n\,dx = \frac{\Gamma(n+1)}{k^{n+1}} = \frac{n!}{k^{n+1}}$, if n is integral. See 109.

118. $\int_0^\infty e^{-k^2x^2}\,dx = \sqrt{\pi}/(2k).$

119. $\int_0^\infty e^{-k^2x^2}\cos mx\,dx = \frac{\sqrt{\pi}\,e^{-m^2/4k^2}}{2k}$, if $k>0$.

120. $\int_0^\infty \frac{2\,dx}{e^{kx}+e^{-kx}} = \int_0^\infty \frac{dx}{\cosh kx} = \frac{\pi}{2k}.$ 121. $\int_0^1 (\log x)^n\,dx = (-1)^n n!$

122. $\int_0^{\pi/2} \log\sin x\,dx = \int_0^{\pi/2}\log\cos x\,dx = -\frac{\pi}{2}\log 2.$

123. $\int_0^{\pi/2}\sin^{2n+1}x\,dx = \int_0^{\pi/2}\cos^{2n+1}x\,dx = \frac{2\cdot4\cdot6\cdots2n}{3\cdot5\cdot7\cdots(2n+1)}$ (n, positive integer.)

124. $\int_0^{\pi/2}\sin^{2n}x\,dx = \int_0^{\pi/2}\cos^{2n}x\,dx = \frac{1\cdot3\cdot5\cdots(2n-1)}{2\cdot4\cdot6\cdots2n}\frac{\pi}{2}$ (n, positive integer.)

G. Approximation Formulas.

125. $\int_a^b f(x)\,dx = f(c)(b-a),\quad a<c<b.$ [**Law of the Mean.**]

126. $\int_a^b f(x)\,dx = \frac{f(b)+f(a)}{2}(b-a).$ [**Trapezoid Rule** — precise for a straight line.]

127. $\int_a^b f(x)\,dx.$ [*Extended Trapezoid Rule.*]

$$=[f(a)/2+f(a+\Delta x)+f(a+2\Delta x)+\cdots+f[a+(n-1)\Delta x]+f(b)/2]\Delta x.$$

128. $\int_a^b f(x)\,dx = \frac{f(a)+4f[(a+b)/2]+f(b)}{6}(b-a).$

[**Prismoid Rule**; or *second Simpson-Lagrange* approximation; precise if $f(x)$ is any quadratic or cubic; see § 124, p. 202.]

129. $\int_a^b f(x)dx = \frac{\Delta x}{3}[f(a)+4f(a+\Delta x)+2f(a+2\Delta x)$
$+4f(a+3\Delta x)+2f(a+4\Delta x)+\cdots+f(b)].$

[**Simpson's Rule**; or extended prismoid rule. Ex. 13, p. 207.]

130. $\int_a^b f(x)\,dx$

$$= \frac{f(a)+3f[a+\Delta x]+3f[a+2\,\Delta x]+f(b)}{8}(b-a)\,;\ \Delta x=(b-a)/3.$$

[A *third Simpson-Lagrange Approximation.* Extend as in 129.]

131. $\int_a^b f(x)\,dx$

$$= \frac{7f(a)+32f[a+\Delta x]+12f[a+2\,\Delta x]+32f[a+3\,\Delta x]+7f(b)}{90}(b-a);\ \Delta x=(b-a)/4.$$

[A *fourth Simpson-Lagrange Approximation;* see *Lagrange interpolation formula,* II, I, 17, p. *15.*]

H. Standard Applications of Integration.

132. *Areas of Plane Figures:* $\int dA.$

(*a*) Strips ΔA parallel to y-axis: $dA = y\,dx.$

(*b*) Strips ΔA parallel to x-axis: $dA = x\,dy.$

(*c*) Rectangles $\Delta A = \Delta x\,\Delta y$: $dA = dx\,dy,\ A = \iint dx\,dy.$

(*d*) Parameter form of equation: $A = (1/2)\int (x\,dy - y\,dx).$

(*e*) Polar sectors bounded by radii: $dA = (\rho^2/2)\,d\theta.$

(*f*) Polar rectangles $\Delta A = \rho\,\Delta\rho\,\Delta\theta$: $dA = \rho\,d\rho\,d\theta\,;\ A = \iint \rho\,d\rho\,d\theta.$

133. *Lengths of Plane Curves:* $\int ds.$

(*a*) Equation in form $y = f(x)$: $ds = \sqrt{1+[f'(x)]^2}\,dx.$

(*b*) Equation in form $x = \phi(y)$: $ds = \sqrt{1+[\phi'(y)]^2}\,dy.$

(*c*) Parameter equations: $ds = \sqrt{dx^2+dy^2}.$

(*d*) Polar equation: $ds = \sqrt{d\rho^2+\rho^2\,d\theta^2}.$

134. *Volumes of Solids:* $\int dV.$

(*a*) *Frustum* (area of cross section A): $dV = A\,dh\,;\ V = \int A\,dh$ where h is the variable height perpendicular to the cross section A.

(*b*) Solid of revolution about x-axis: $dV = \pi y^2\,dx.$

(*c*) Solid of revolution about y-axis: $dV = \pi x^2\,dy.$

(*d*) Rectangular coördinate divisions: $dV = dx\,dy\,dz\,;$

$$V = \iiint dz\,dy\,dx = \iint z\,dy\,dx = \int\{\int z\,dy\}\,dx = \int A\,dx.$$

(*e*) Polar coördinate divisions: $dV = \rho^2 \sin\theta\,d\rho\,d\phi\,d\theta.$

135. *Area of a Surface:* $\int\int \sec\psi\, dx\, dy,$

where ψ is the angle between the element ds of the surface and its projection $dx\, dy$.

(*a*) Surface of Revolution about x-axis: $A = \int 2\pi y\, ds$.

(*b*) Surface of Revolution about y-axis: $A = \int 2\pi x\, ds$.

136. *Length of twisted arcs:* $\int ds.$

(*a*) Rectangular Coördinates: $ds = \sqrt{dx^2 + dy^2 + dz^2}$.

(*b*) Explicit Equations $y = f(x)$, $z = \phi(x)$: $ds = \sqrt{1 + [f'(x)]^2 + [\phi'(x)]^2}$.

(*c*) $x = f(t)$, $y = \phi(t)$, $z = \psi(t)$: $ds = \sqrt{[f'(t)]^2 + [\phi'(t)]^2 + [\psi'(t)]^2}$.

(*d*) Polar Coördinates: $ds = \sqrt{d\rho^2 + \rho^2 d\phi^2 + \rho^2 \cos^2\phi\, d\theta^2}$.

137. *Mass of a body:* $M = \int dM = \int \rho\, dV,$

where ρ is the density (mass per unit volume).

(*a*) If ρ is constant: $M = \rho \int dV$; see 134.

(*b*) On any curve: $dV = ds$, if ρ = mass per unit length.

(*c*) On any surface (or plane): $dV = dA$, if ρ = mass per unit area.

138. *Average value of a variable quantity q:* **A. V. of q.:**

(*a*) throughout a solid: $q = f(x, y, z)$; $A.\,V.$ of $q. = \int q\, dV \div \int dV$.

(*b*) on an area A: $A.\,V.$ of $q. = \int q\, dA \div \int dA$.

(*c*) on an arc s: $A.\,V.$ of $q. = \int q\, ds \div \int ds$.

139. *Center of Mass,* $(\bar{x}, \bar{y}, \bar{z})$: $\bar{x} = \int x\, dM \div \int dM,$

with similar formulas for $\bar{y}$ and $\bar{z}$. See dM, 137.

(*a*) for a volume: $dM = \rho\, dV$.

(*b*) for an area: $dM = \rho\, dA$.

(*c*) for an arc: $dM = \rho\, ds$.

139.* *Theorems* of *Pappus* or *Guldin:*

(*a*) Surface generated by an arc of a plane curve revolved about an axis in its plane = length of arc × length of path of center of mass of arc.

(*b*) Volume generated by revolving a closed plane contour about an axis in its plane = area of contour × length of path of its center of mass.

140. *Moment of Inertia:* $I = \int r^2\, dM.$ (See 137, 139.)

(*a*) For plane figures, $I_x + I_y = I_0$, where I_x, I_y, I_0 are taken about the x-axis, the y-axis, the origin, respectively.

(*b*) For space figures, $I_x + I_y + I_z = I_0$.

(*c*) $I_x = I_{\bar{x}} + (x - \bar{x})^2 M$, where $I_{\bar{x}}$ is taken about a line || to the x-axis.

141. *Radius of Gyration:* $k^2 = I \div M = \int r^2\,dM \div \int dM.$

[In 140 and 141, r may be the distance from some fixed point, or line, or plane.]

142. *Liquid pressure:* $P = \int \rho h\,dA,$

where P is the total pressure, dA is the elementary strip parallel to the surface; h is the depth below the surface; and ρ is the weight per unit volume of the liquid.

143. *Center of liquid pressure:* $\bar{h} = \int h^2 dA \div \int h dA.$

144. *Work of a variable force:* $W = \int f \cos\psi\,ds,$

where f is the numerical magnitude of the force, ds is the element of the arc of the path, and ψ is the angle between f and ds.

145. *Attraction exerted by a solid:* $F = k \int \frac{m\,dM}{r^2},$

where k is the attraction between two unit masses at unit distance, m is the attracted particle, dM is an element of the attracting body; r is the distance from m to dM.

Components F_x, F_y, F_z of F along Ox, Oy, Oz are:

$$F_x = km \int \frac{\cos\alpha\,dM}{r^2}, \quad F_y = km \int \frac{\cos\beta\,dM}{r^2}, \quad F_z = km \int \frac{\cos\gamma\,dM}{r^2},$$

where α, β, γ are the direction angles of a line joining m to dM.

146. *Work in an expanding gas:* $W = \int p\,dv.$

147. *Distance s, speed v, tangential acceleration j_T:*

$$j_T = \int v\,dt = \int \left\{ \int s\,dt \right\} dt.$$

[Similar forms for angular speed and acceleration.]

148. *Errors of observation:*

(*a*) Probability of an error between $x = a$ and $x = b$: $P = \int_{x=a}^{x=b} y\,dx$, where y is the probable number of errors of magnitude x.

(*b*) The usual formula $y = (h/\sqrt{\pi})e^{-h^2x^2}$ gives: $P = (h/\sqrt{\pi})\int e^{-h^2x^2}dx$, where h is the so-called *measure of precision*.

(*c*) Probability of an error between $x = -a$ and $x = +a$: $P(a) = \int_{x=-a}^{x=a} y\,dx.$

(*d*) *Probable error* $= (0.477)/h =$ value of a for which $P(a) = 1/2$.

(*e*) *Mean error* $= \int_0^\infty xy\,dx + \int_0^\infty y\,dx = 1/(h\sqrt{\pi})$.

V. NUMERICAL TABLES

$\log_e x = (\log_{10} x) \div M$; $M = .4342944819$. $\log_{10} e^{x+y} = \log_{10} e^x + \log_{10} e^y$.

Sinh x and cosh x approach $e^x/2$ as x increases (see Fig. E, p. *22*). The formula $\log_{10} (e^x/2) = M \cdot x - \log_{10} 2$ represents $\log_{10} \sinh x$ and $\log_{10} \cosh x$ to three decimal places when $x > 3.5$; four places when $x > 5$; to five places when $x > 6$; to eight places when $x > 10$.

D. VALUES OF

$$F(k, \phi) = \int_0^\phi \frac{d\theta}{\sqrt{1-k^2\sin^2\theta}} = \int_0^u \frac{dx}{\sqrt{(1-x^2)(1-k^2x^2)}}, \quad \begin{Bmatrix} x = \sin\theta \\ u = \sin\phi \end{Bmatrix}.$$

F. VALUES OF $\Pi(p) = \Gamma(p+1) = \int_0^\infty e^{-x} x^p dx$

p A PROPER FRACTION

[$\Pi(n) = \Gamma(n+1) = n!$, if n is a positive integer.]

	$p=0.0$	$p=0.1$	$p=0.2$	$p=0.3$	$p=0.4$	$p=0.5$	$p=0.6$	$p=0.7$	$p=0.8$	$p=0.9$
$\Gamma(p+1)=$	1.000	0.951	0.918	0.897	0.887	$0.886=\sqrt{\pi}/2$	0.894	0.909	0.931	0.962

$\Gamma(k+1) = k\Gamma(k)$, if $k > 0$; hence $\Gamma(k+1)$ can be calculated at intervals of 0.1. Minimum value of $\Gamma(p+1)$ is .88560 at $p = .46163$.

G. VALUES OF THE PROBABILITY INTEGRAL: $\frac{2}{\sqrt{\pi}}\int_0^x e^{-x^2} dx$.

x	.0	.1	.2	.3	.4	.5	.6	.7	.8	.9

* $B_n \equiv n$th Bernoulli number; see II, E, 15–18, p. *8*.

† Exact legal values in U. S.

INDEX

[Numbers in roman type refer to pages of the body of the book; those in italics refer to pages of the *Tables*.]

ANSWERS TO EXERCISES

§ 6. Page 9

1. $y = 2x - 3$. **3.** $8x - y = 11$. **5.** $3x - y = 2$. **7.** $3x + y = 4$.

§ 9. Page 12

3. 82 ; 114 ; 178 ; $50 + 32\,T$. **5.** 2 ; 6 ; 40 ; $2\,T$. **7.** 80 ; 16 ; -80.
9. $t = 5/2$; $s = 100$; $v = 0$. **11.** 1 ; $2t$; $\sqrt{1 + 4t^2}$.

§ 11. Pages 17–18

5. 9. **7.** $-5/12$. **9.** $-1/2$. **11.** $(a+b)/(c+d)$. **13.** 1.
15. 0. **17.** 3/5. **19.** $-1/2$. **23.** 5/3. **25.** 2. **27.** $\sqrt{a}/p$.

§ 14. Pages 22–23

1. $2x - 4$. **3.** $3 - 3x^2$. **5.** $8 - 4x^3$. **7.** $-1/(x-1)^2$.
9. $-2/x^3$. **11.** $8/(x+2)^2$. **13.** $4x + 9y = 24$. **15.** Rises when $|x| > \sqrt{5}$; falls when $|x| < \sqrt{5}$; slope zero when $x = \pm\sqrt{5}$.
17. Rises when $x > 2$; falls when $x < 2$; slope zero when $x = 2$.
19. Hor. speed, $dx/dt = 15$; vert. speed, $dy/dt = -32\,t + 15$.
21. $8\pi r$; $3\,a^2$; $2\,\pi rh/3$.

§ 16. Pages 27–28

1. $12\,x^3$. **3.** $20\,x^4$. **5.** $50\,(t^4 + 1)$. **7.** $12\,t(t^2 - 1)$.
9. $18\,t^2(1 + t^3)$. **11.** $6\,r\,(3\,r + 2)$. **13.** $2\,v - 1$. **15.** $11\,v^{10} + 12\,v^5$.
17. $13\,ay^{12} - 9\,aby^8$. **19.** $mkx^{m-1} + nhx^{n-1}$. **21.** $3\,nt^{3n-1} - (n+2)t^{n+1}$.
23. $(-2, 0)$. **25.** $(1, 6)$. **27.** Slopes at $x = 0, 2, -2, 4, -4$ resp. are 0, 12, 36, 72, 120 ; slope is 9/2 at $x = 3/2$ and $-1/2$; slope is $-3/2$ at $x = 1/2$.

§ 17. Pages 29–30

1. $-1/x^2$. **3.** $6/(x+4)^2$. **5.** $-9/x^4$. **7.** $-28\,x^{-8} - 4\,x^{-3}$.
9. $-(t^4 + 2\,t)/(t^3 - 1)^2$. **11.** $4\,u/(u^2 - 1)^2$. **13.** $16/3 + 1/u^2$.
15. 0. **17.** $-6/z^4 - 6\,z/(z^2 + 1)^2$. **19.** $2(1 - r^2)/(r^2 - r + 1)^2$.
21. $3(1 - 6\,y^2 + 2\,y^3)/(t^3 - 1)^2$. **23.** $-6\,t^{-7} + 3\,t^{-4}$.
25. $-(v^6 + 3\,v^2)/(v^4 - 1)^2$. **27.** $-x/(ax + b)^3$.
29. $(y^2 - 2)/(y - 1)^4$. **31.** $\tan^{-1}(-3)$.

§ 20. Pages 33–34

1. $6x^2 - 2$. **3.** $4x + 3$. **5.** $12x^2 - 5x^4 - 2x$. **7.** $4x(x^2 - 1)$.
9. $6x^2(x^2 - 3)$. **11.** $24x(3x^2 + 5)^3$. **13.** $4(1 - 3t)(1 + 2t - 3t^2)$.
15. $3(3t^2 - 1)(t^3 - t - 4)^2$. **17.** $8(2v^3 + 3v)(v^4 + 3v^2 - 2)$.
19. $-6t^2/(t^3 + 1)^3$. **21.** $(6x^2 - 3x^4 - 18x)/(x^2 + 2)^4$.
23. $-8s(2s^2 - 3)^{-3}$. **25.** $6(2 + 4v^2 - 5v)(3v - 5)(v^2 + 2)^2$.
27. $6t^5 + 12t^3 + 12t^2 + 12$. **29.** $156 - 108x$. **31.** $(2/5)[3(1-2x)^{-2} + 8]$.
33. $3/(2t)$. **35.** Horiz. tangents at $x = 1/2,\ -4/3,\ -5/12$.

§ 23. Pages 37–38

1. $(4/3)x^{\frac{1}{3}}$. **3.** $(4/3)x^{-\frac{1}{3}}$. **5.** $(3/4)x^{-\frac{1}{4}}$. **7.** $-5x^{-2} - 5x^{-\frac{1}{2}}$.
9. $(22/3)t^{\frac{8}{3}} + 7t^{\frac{4}{3}}$. **11.** $-6x^{-4} - (1/2)x^{\frac{3}{2}} + (2/3)x^{-\frac{1}{3}}$.
13. $\dfrac{3}{2\sqrt{2 + 3x}}$. **15.** $\dfrac{4 + 9u}{2\sqrt{2 + 3u}}$. **17.** $\dfrac{2t - 3}{2\sqrt{t^2 - 3t}}$.
19. $\dfrac{2x}{3(1 + x^2)^{\frac{2}{3}}}$. **21.** $\dfrac{15x^2 - 16x}{2\sqrt{3x - 4}}$. **23.** $\dfrac{2x - 1}{2\sqrt{1 - x + x^2}}$.
25. $\dfrac{1}{4\sqrt{x + x\sqrt{x}}}$. **27.** $\dfrac{u - 2a^2}{2u^2\sqrt{a^2 - u}}$. **29.** $\dfrac{t - 3t^3}{\sqrt{1 - t^2}}$.
31. $2(x + \sqrt{1 + x^2})^2/\sqrt{1 + x^2}$. Tangents: **33.** $3x + 4y = 5$.
35. $2\sqrt{2}y - x = 2$. **37.** $2\sqrt{2}y = 5x - 1$. **39.** $\tan^{-1}(5/12)$.
41. $dp/dv = -1.41\,kv^{-2.41}$.

§ 25. Pages 41–42

1. $-2y/x$ or $-2/x^3$. **3.** $(2x - y)/x$ or $1 + 5/x^2$.
5. $x/4y$ or $x/(2\sqrt{x^2 - 36})$. **7.** $-x^2/y^2$ or $-x^2/(a^3 - x^3)^{\frac{2}{3}}$.
9. $3(1 - x^2)/(2y)$ or $3(1 - x^2)/2\sqrt{3x - x^3}$.
11. $(2x - y^2)/(2y + 2xy)$ or $(2 + x)/2(1 + x)^{\frac{3}{2}}$. **13.** $-y/x$.
15. $1/(2y)$. **17.** $-\sqrt{y/x}$. **19.** $4t$; $2y = x^2$.
21. t; $27y^2 = 4(x - 1)^3$. **23.** $(t^2 - 1)/(2t)$; $x^2 + y^2 = 1$.
27. $dy/dx > 0$ when $x < 0$ and $v.\,v.$ **29.** $v = (1/2)\sqrt{2 + 2t^2}$.

§ 27. Pages 46–48

1. $(2ax + b)dx$. **3.** $3(2ax + b)(ax^2 + bx + c)^2dx$. **5.** $-a(ax + b)^{-2}dx$.
7. $-(12t + 1)dt$. **9.** $t(a - t)^2(2a - 5t)dt$. **11.** $(3 - 2t)dt/2\sqrt{3t - t^2}$.
13. $(9/2)\sqrt{t^3 - 3t}(t^2 - 1)dt$. **15.** $-(1 + v)dv/(2v + v^2)^{\frac{3}{2}}$.
17. $-(1 + v)(2 + 3v^2 + v^3)dv/(v^3 - 1)^2$. **19.** $4y^2(2 - y^3)^{-\frac{7}{3}}dy$.

21. $(1/2)(2+y)(1+y)^{-\frac{3}{2}}dy$. **23.** $bnps^{n-1}(a+bs^n)^{p-1}ds$.
25. $-bnps^{n-1}ds/(a+bs^n)^{p+1}$. **27.** $dx/[\sqrt{x}(1-\sqrt{x})^2]$.
29. $\dfrac{ydx}{1-x}$. **31.** $\dfrac{(2x^3-xy^2-x)dx}{y+x^2y}$. **33.** $\dfrac{a(x^2+y^2)dx}{2y(1-ax)}$.
35. $\dfrac{(3bx^2+2ax+by^2)dx}{2y(a-bx)}$. **37.** $y+6x=11$. **43.** $\sqrt{t/2}$.
45. $-(2+\theta)(1+\theta)^2/\theta^3$. **47.** $9/(2r)$. **49.** $2(1-t^2)/(1+t^2)^2$; $-4t/(1+t^2)^2$; $2/(1+t^2)$. **51.** $dv=(b-v)dp/(p-a/v^2+2ab/v^3)$.

§ 31. Page 52

	Tang.	Norm.	Subt.	Subn.	Tang.	Norm.
1.	$9x+y=5$.	$x-9y=37$.	4/9.	36.	$4\sqrt{82}/9$.	$4\sqrt{82}$.
3.	$9x+4y=25$.	$9y-4x=32$.	16/9.	9.	$4\sqrt{97}/9$.	$\sqrt{97}$.
